

# Programming Using Java

Session 9: Collections and Concurrency

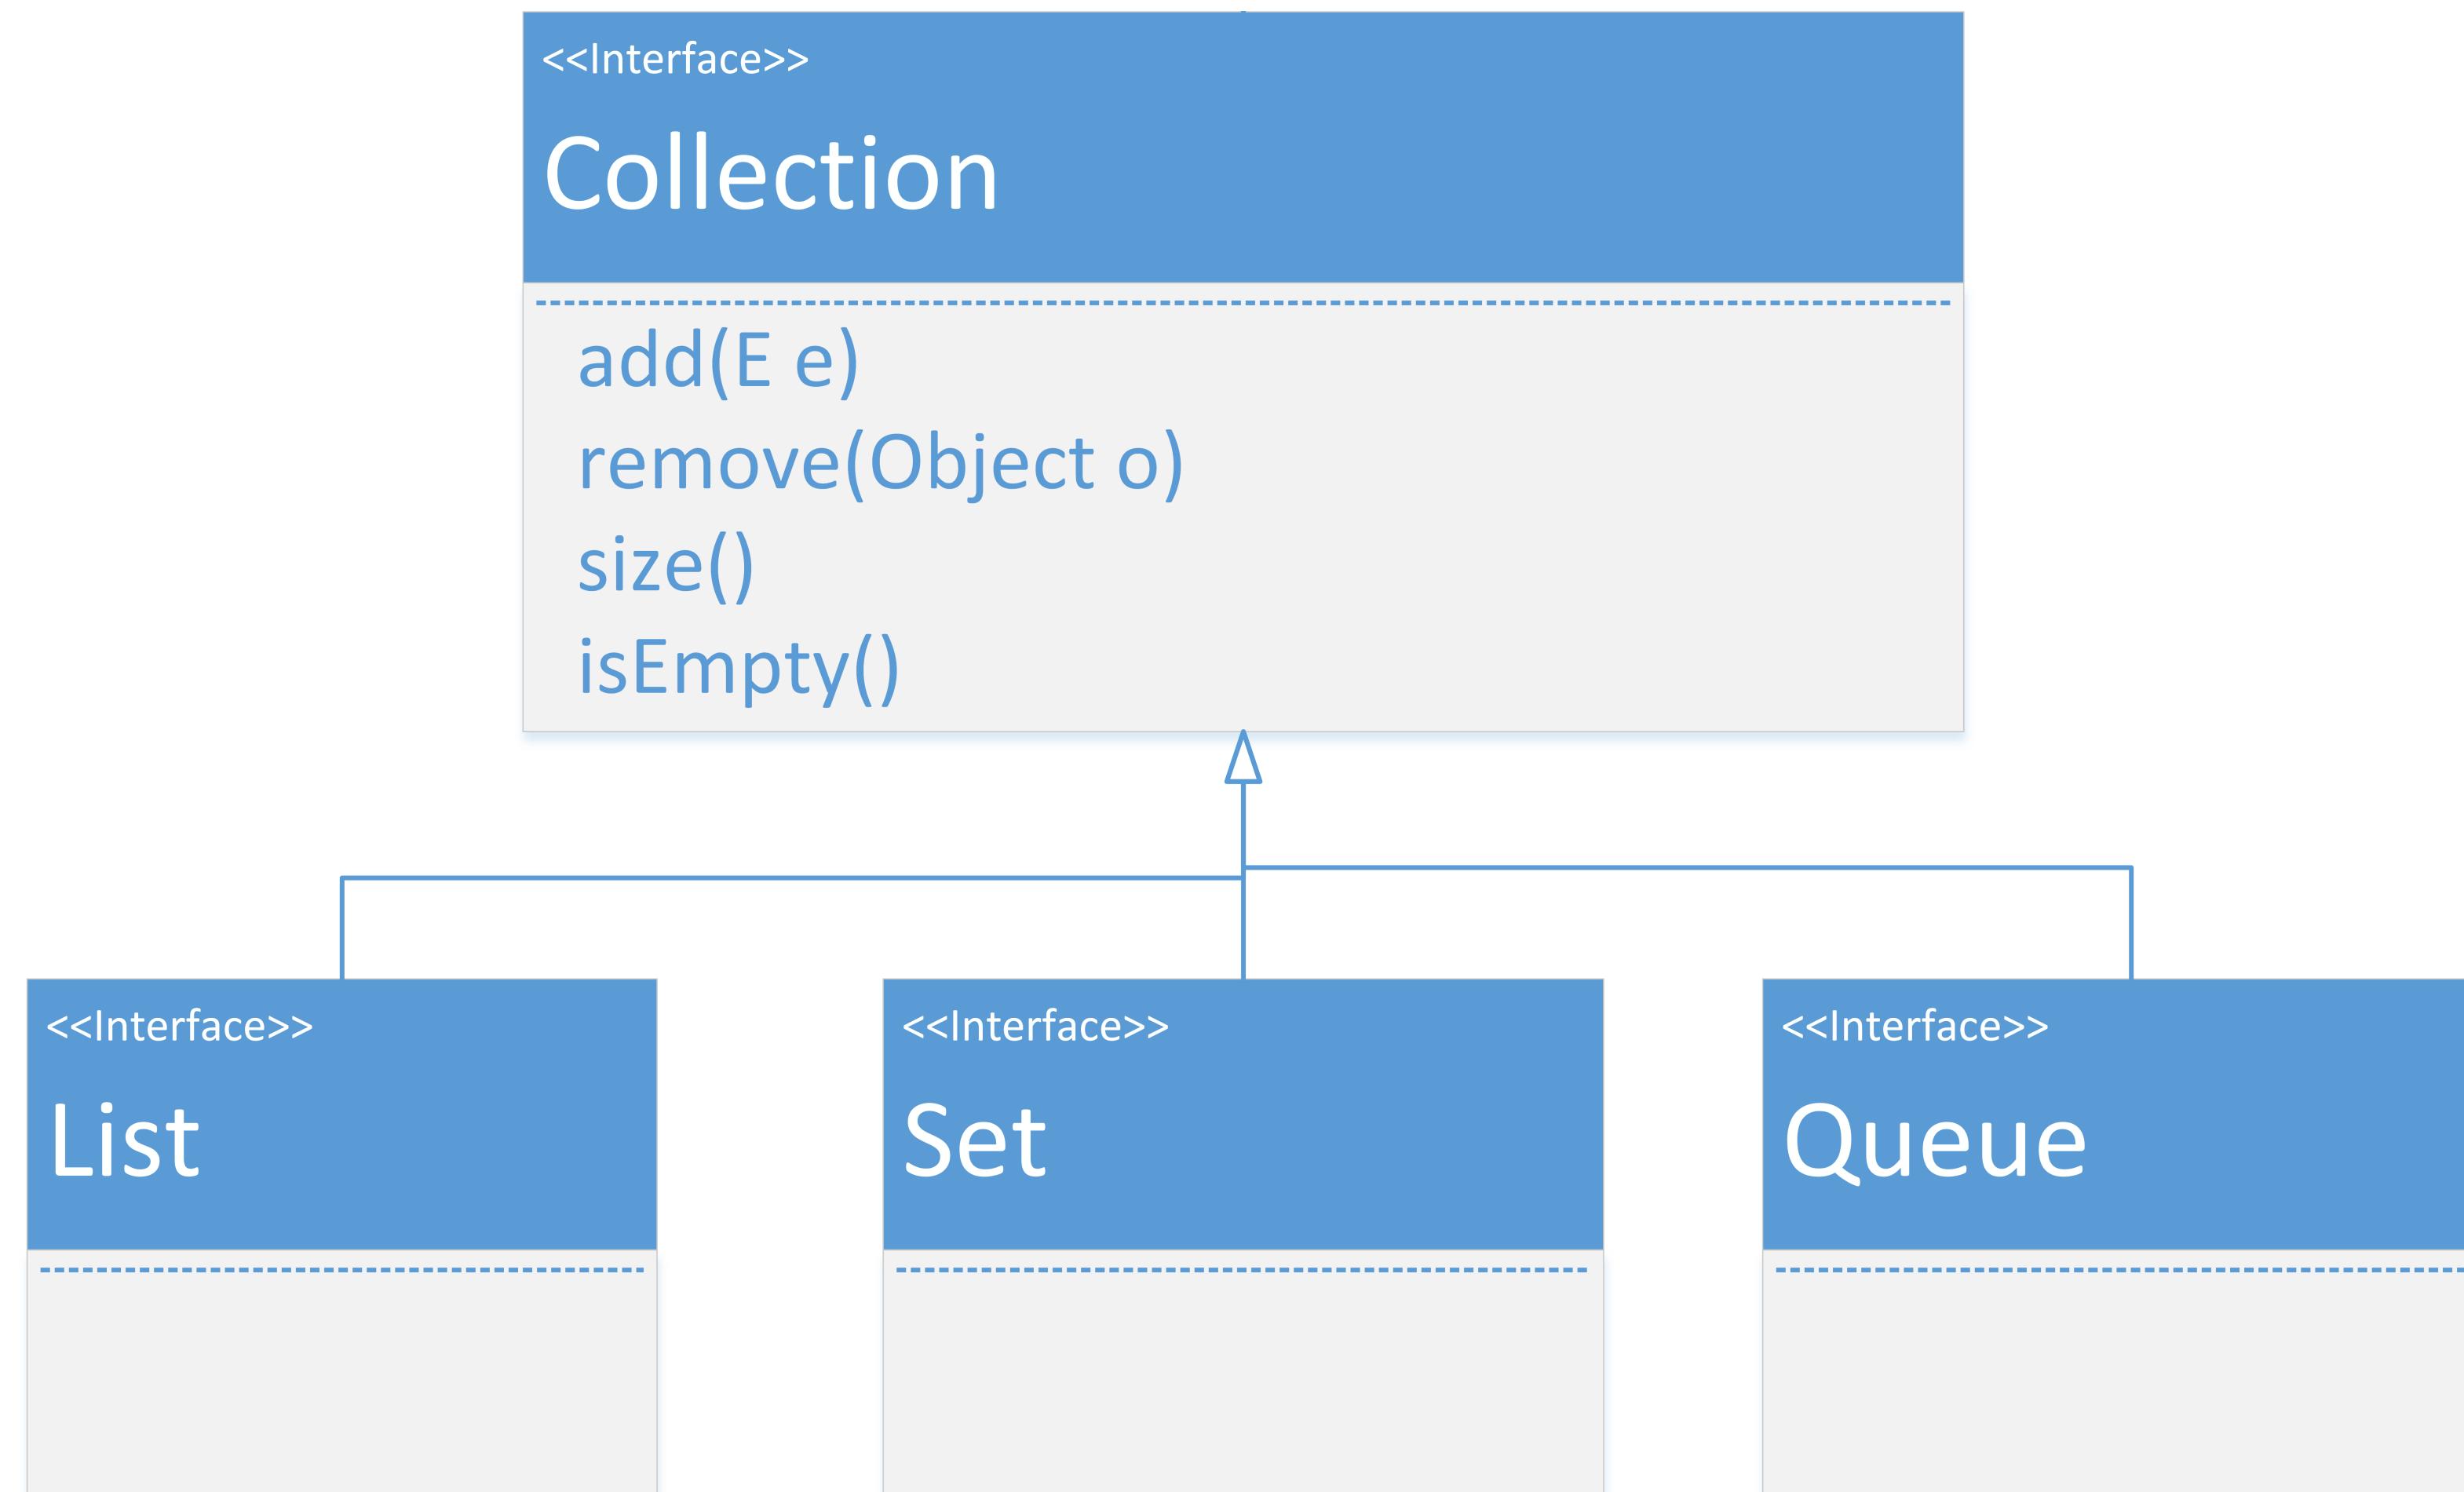

# Collections

“...data structure that holds object references...”

| Interface  | Description  |
|------------|--|
| Collection | root interface   |
| Set        | contains no duplicates   |
| List       | ordered collection, can contain duplicates                     |
| Map        | has keys associated with values, duplicate keys are disallowed |
| Queue      | first-in, first-out, models waiting line                       |

# Collection Interfaces

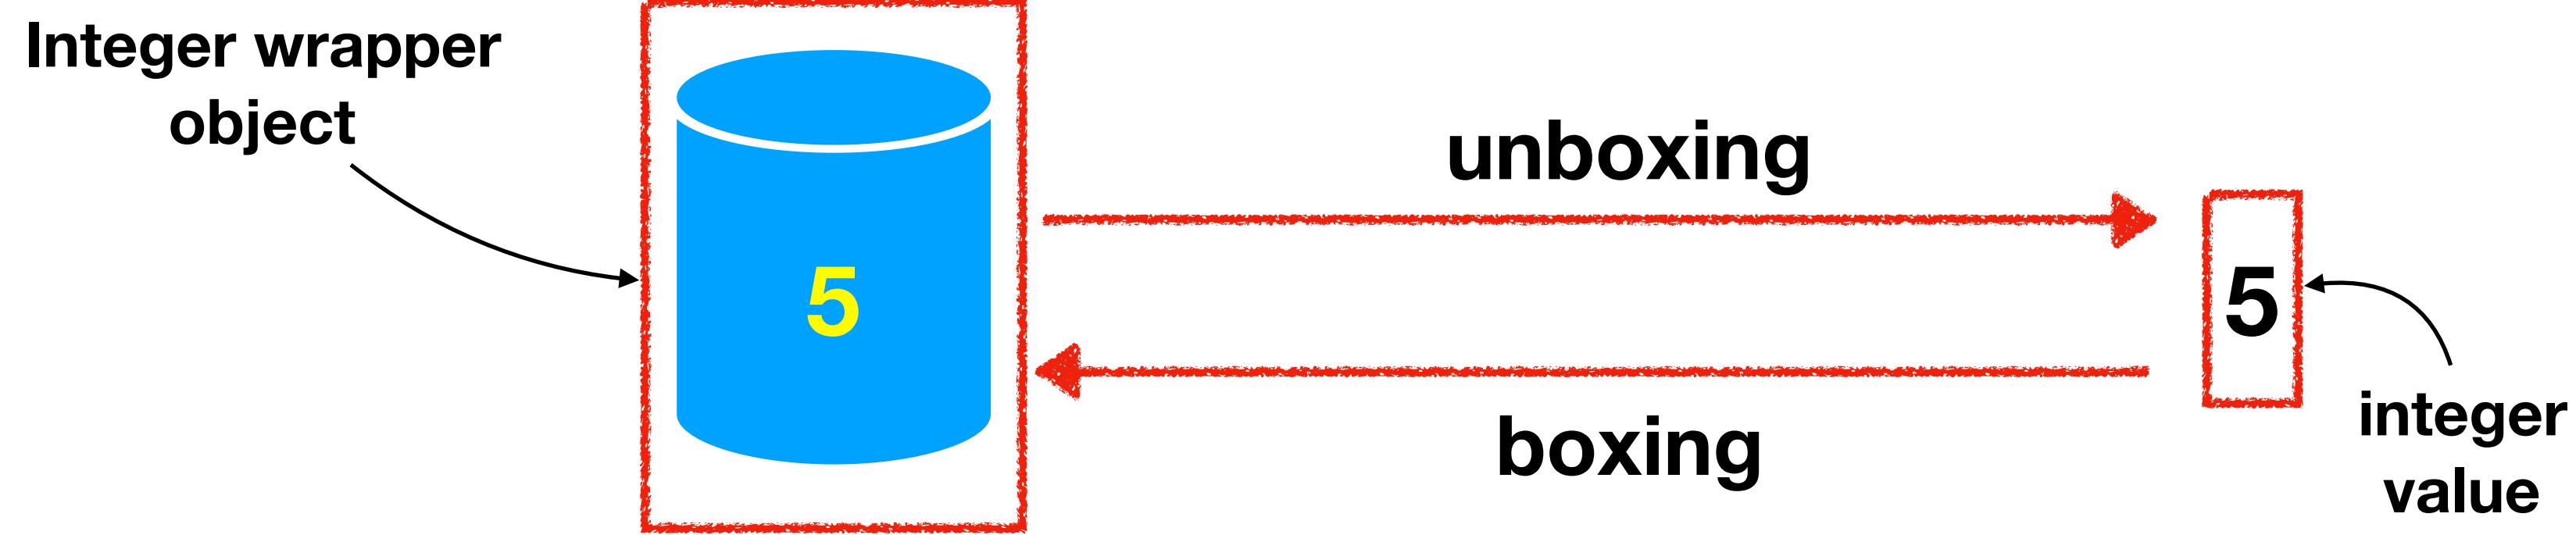

“...defines operations which can be performed...”

# Collection Hierarchy

# Autoboxing

- primitive types have a related wrapper class
- conversion between primitive value and wrapper object is automatic
- wrapper classes contain utility methods

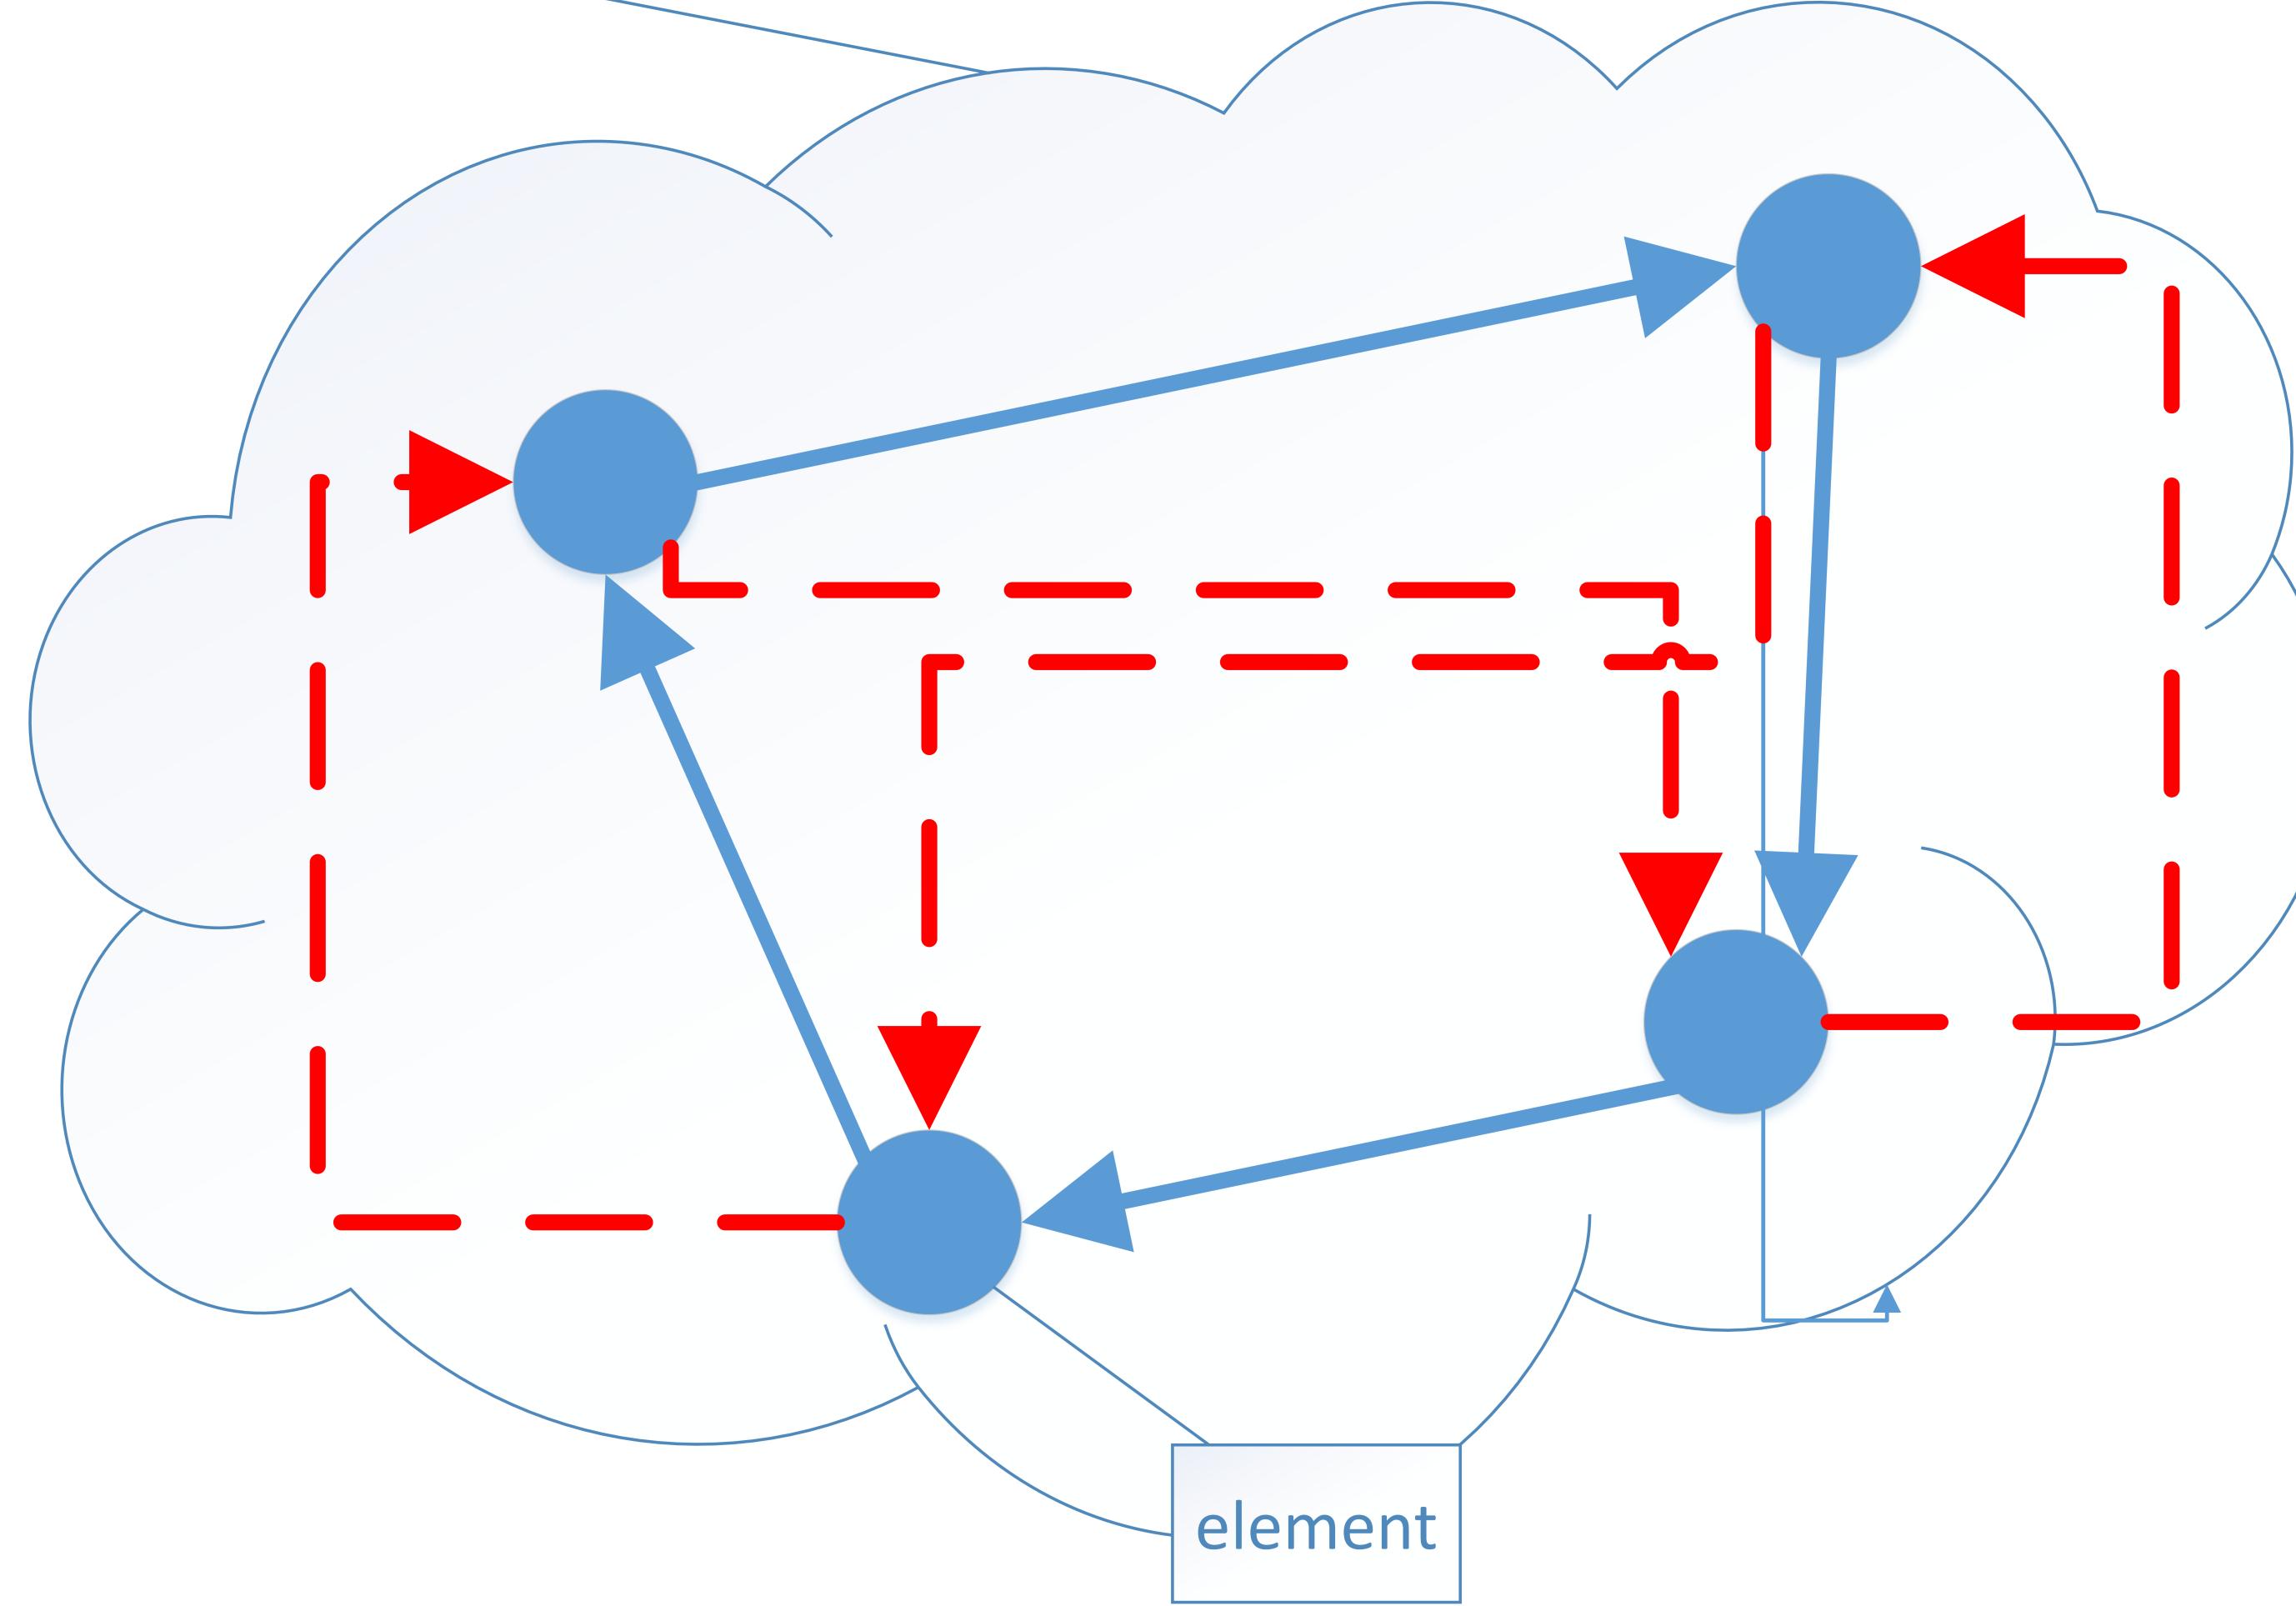

```
class MyClass {  
    public static void main() {  
  
        Integer i[] = new Integer[5];  
        i[1] = 5; ← autoboxing  
        int intValue = i[1];  
        ↑ unboxing  
  
        int convertedInt = Integer.parseInt("5");  
    }  
}
```

# Collection Interface

- cannot store primitive types, only object references
- has operations performed on whole collection
- provides access to Iterator object
- Collections class has a set of static methods

```
public class CollectionSample {  
  
    public static void main(String[] args) {  
  
        Collection<Integer> c = new ArrayList<>();  
        System.out.println("empty?" + c.isEmpty());  
        c.add(1); c.add(2); c.add(3);  
  
        System.out.println("5 exists?" + c.contains(5));  
        System.out.println("empty?" + c.isEmpty());  
        System.out.println("size:" + c.size());  
  
        Iterator i = c.iterator();  
        while(i.hasNext())  
            System.out.println("element:" + i.next());  
  
        System.out.println("max:" + Collections.max(c));  
    }  
}
```

collection

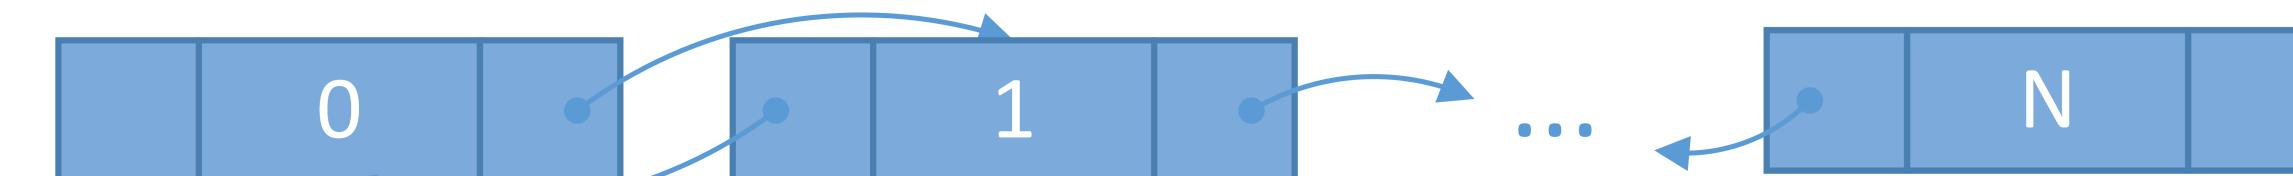

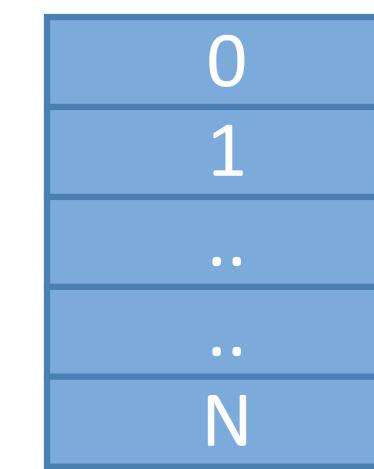

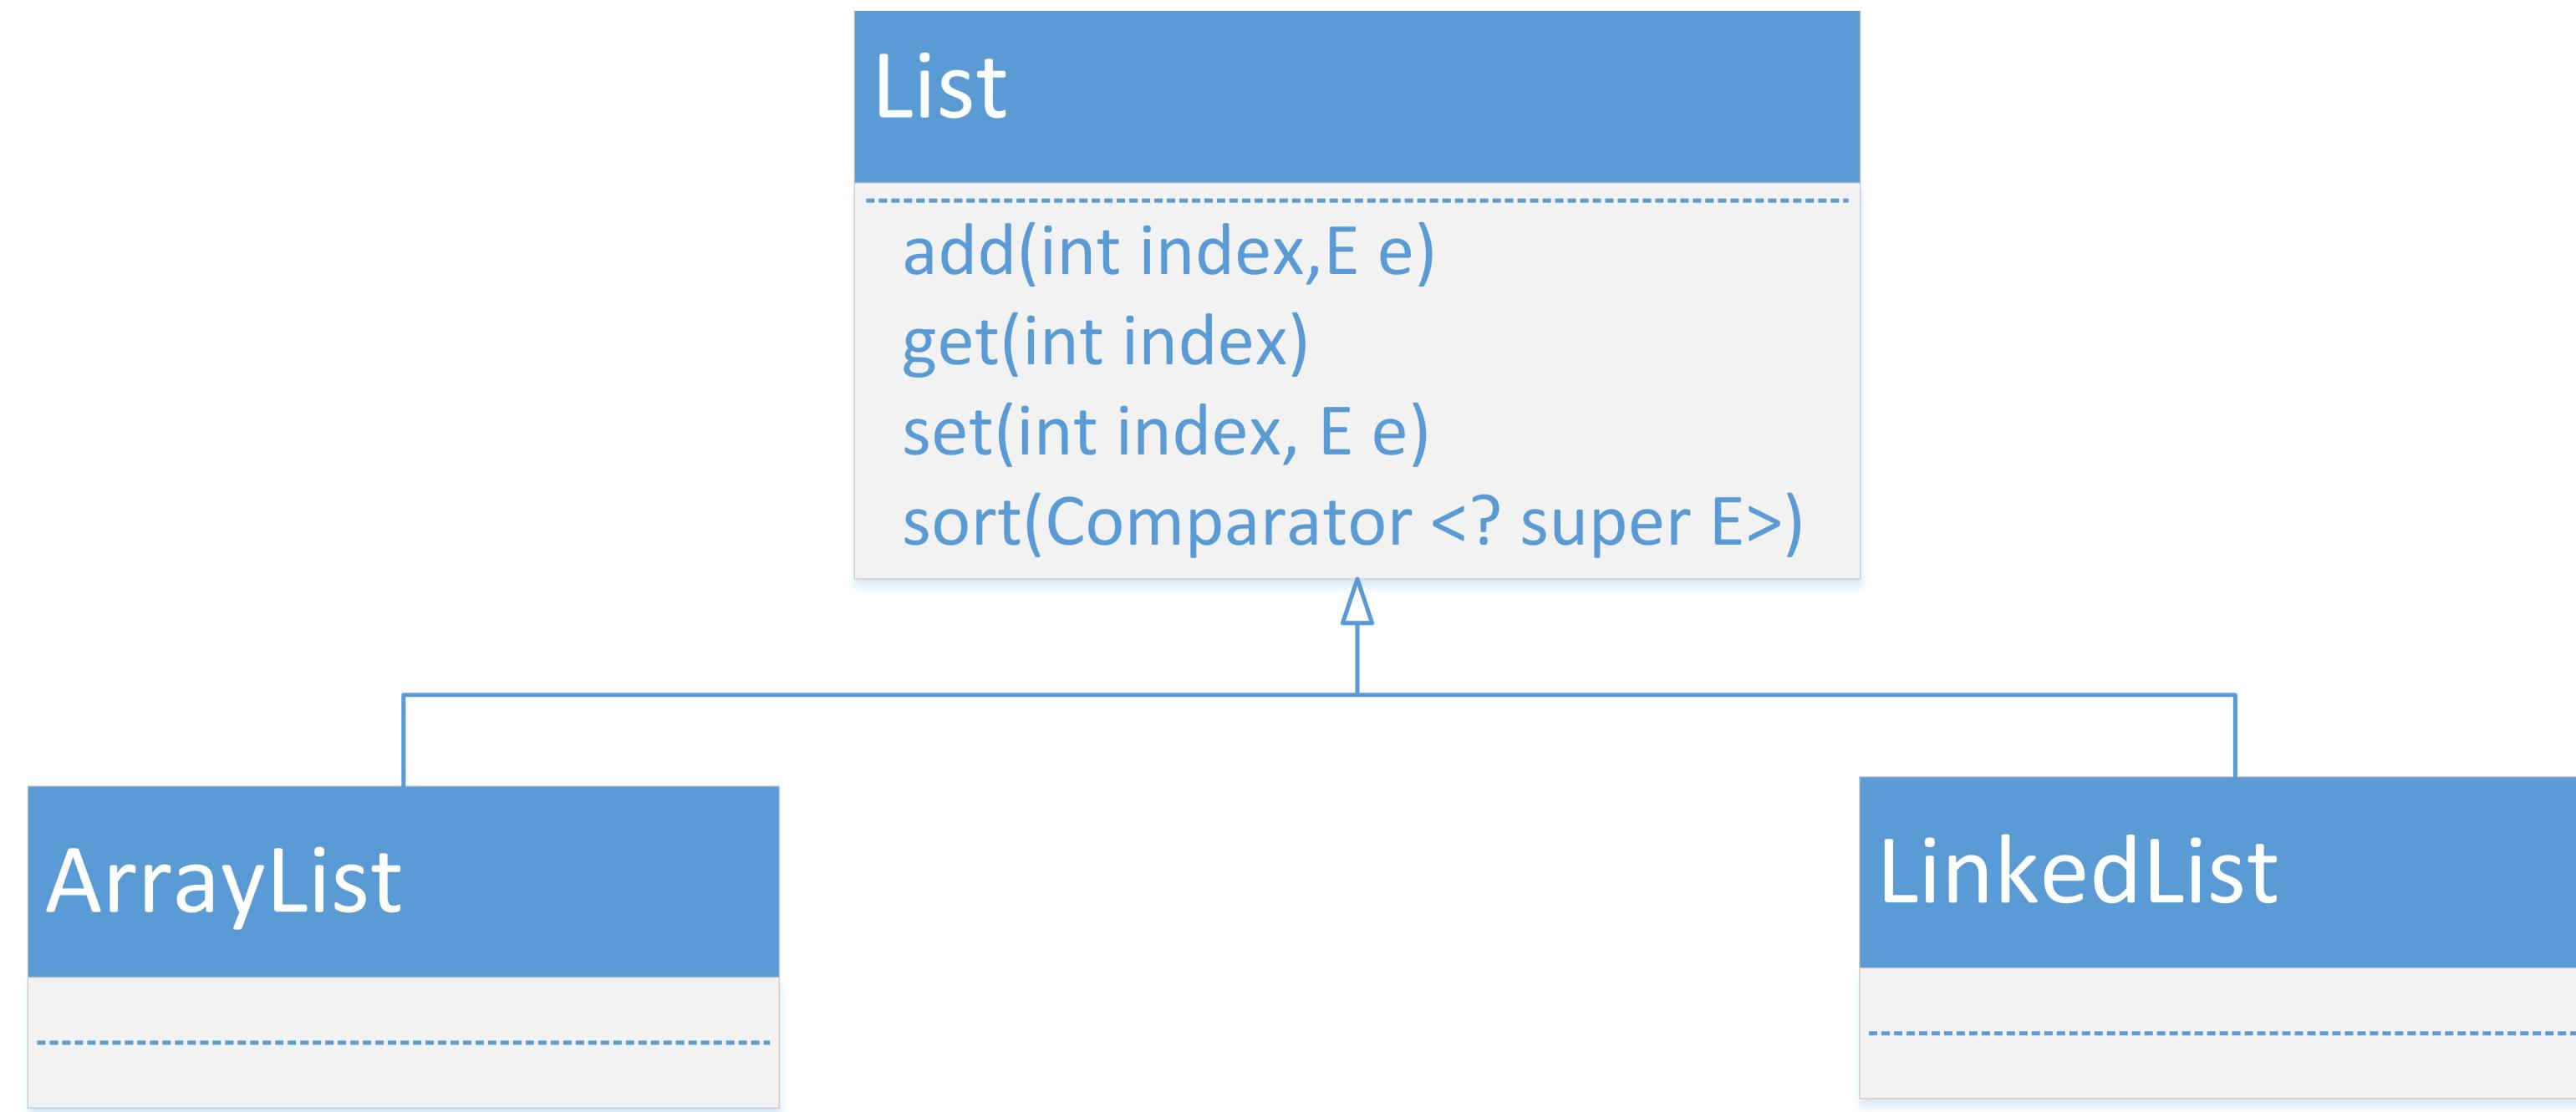

# Iterators

“...object which allows traversal of elements...”

# List Interface

- sequential collection
- elements accessed by index
- similar to array functionality except resizable

```
public class ListExample {  
    public static void main(String[] args) {  
  
        List<Integer> intList = new ArrayList<>();  
        intList.add(1); intList.add(0,2);intList.add(3);  
        List<String> subList =  
            intList.subList(1, intList.size());  
  
        // print all elements  
        Iterator<String> it = intList.iterator();  
        while(it.hasNext()) System.out.println(it.next());  
  
        // alternate implementation  
        intList.forEach(System.out::println);  
    } }
```

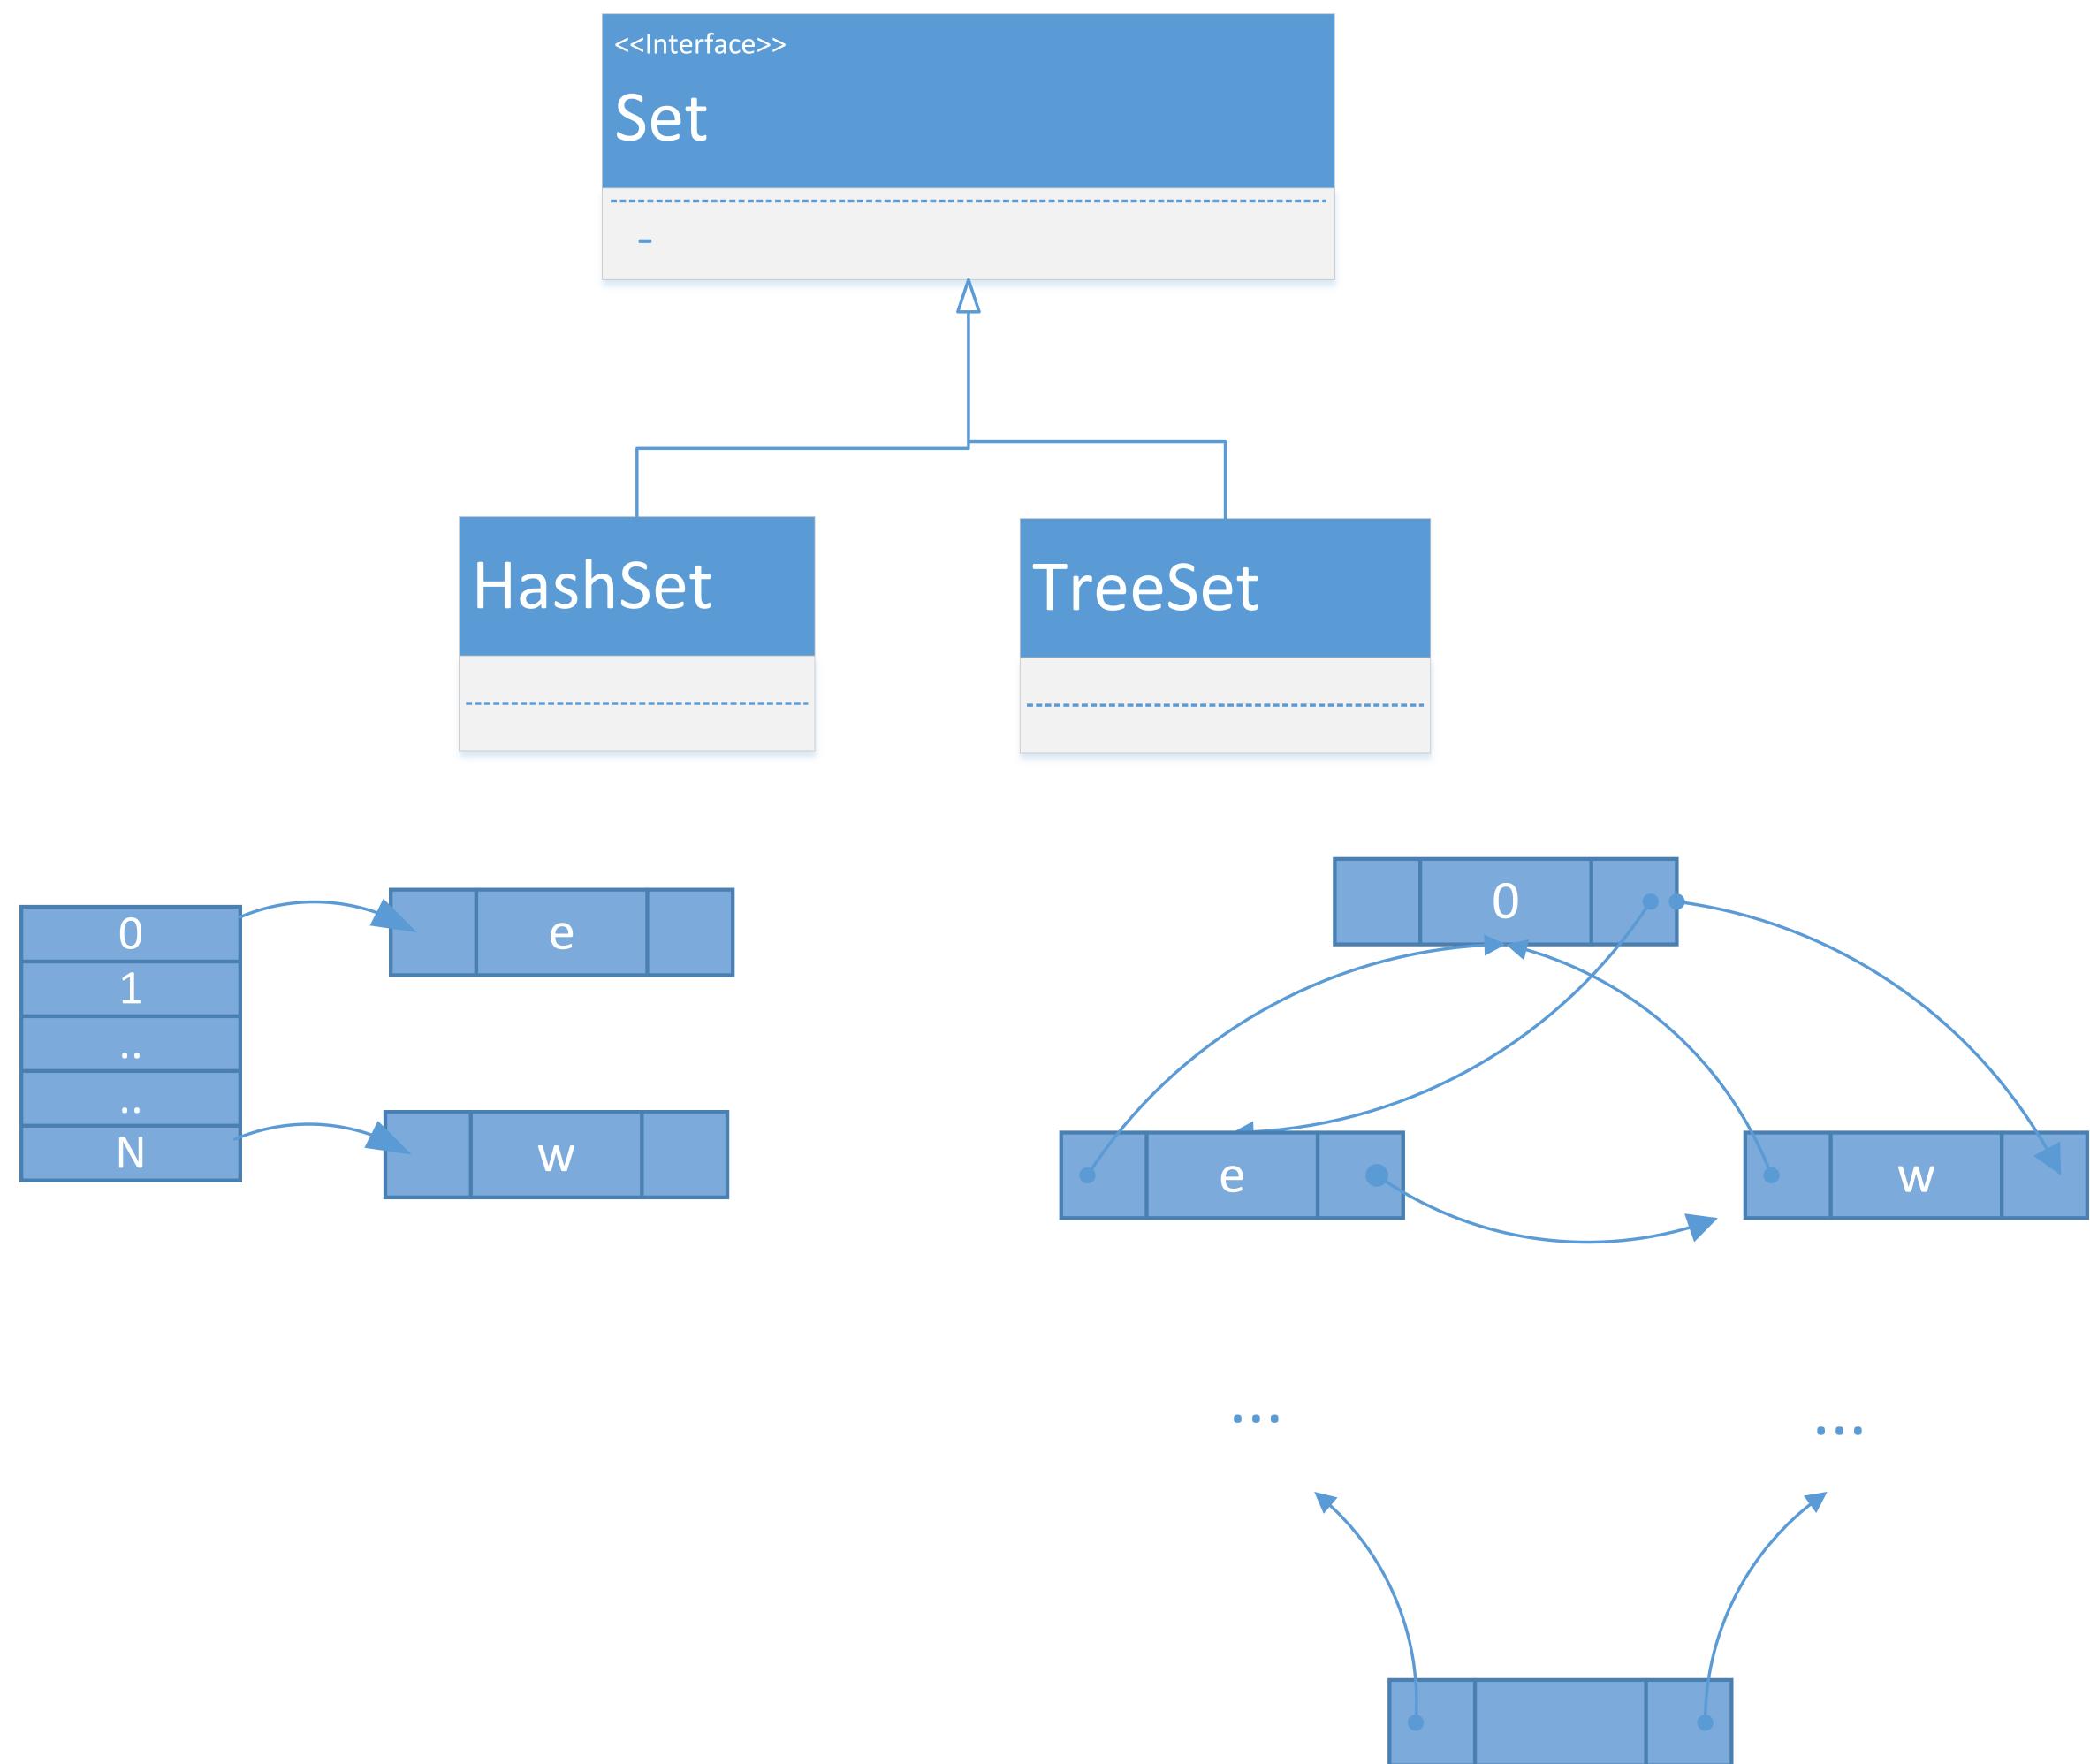

# List Implementations

“...optimized per use case...”

# Set Interface

- 📌 unordered structure with no duplicates...
- 📌 main operation is membership test
- 📌 useful for other set-algebraic operations (union, intersection, ...)

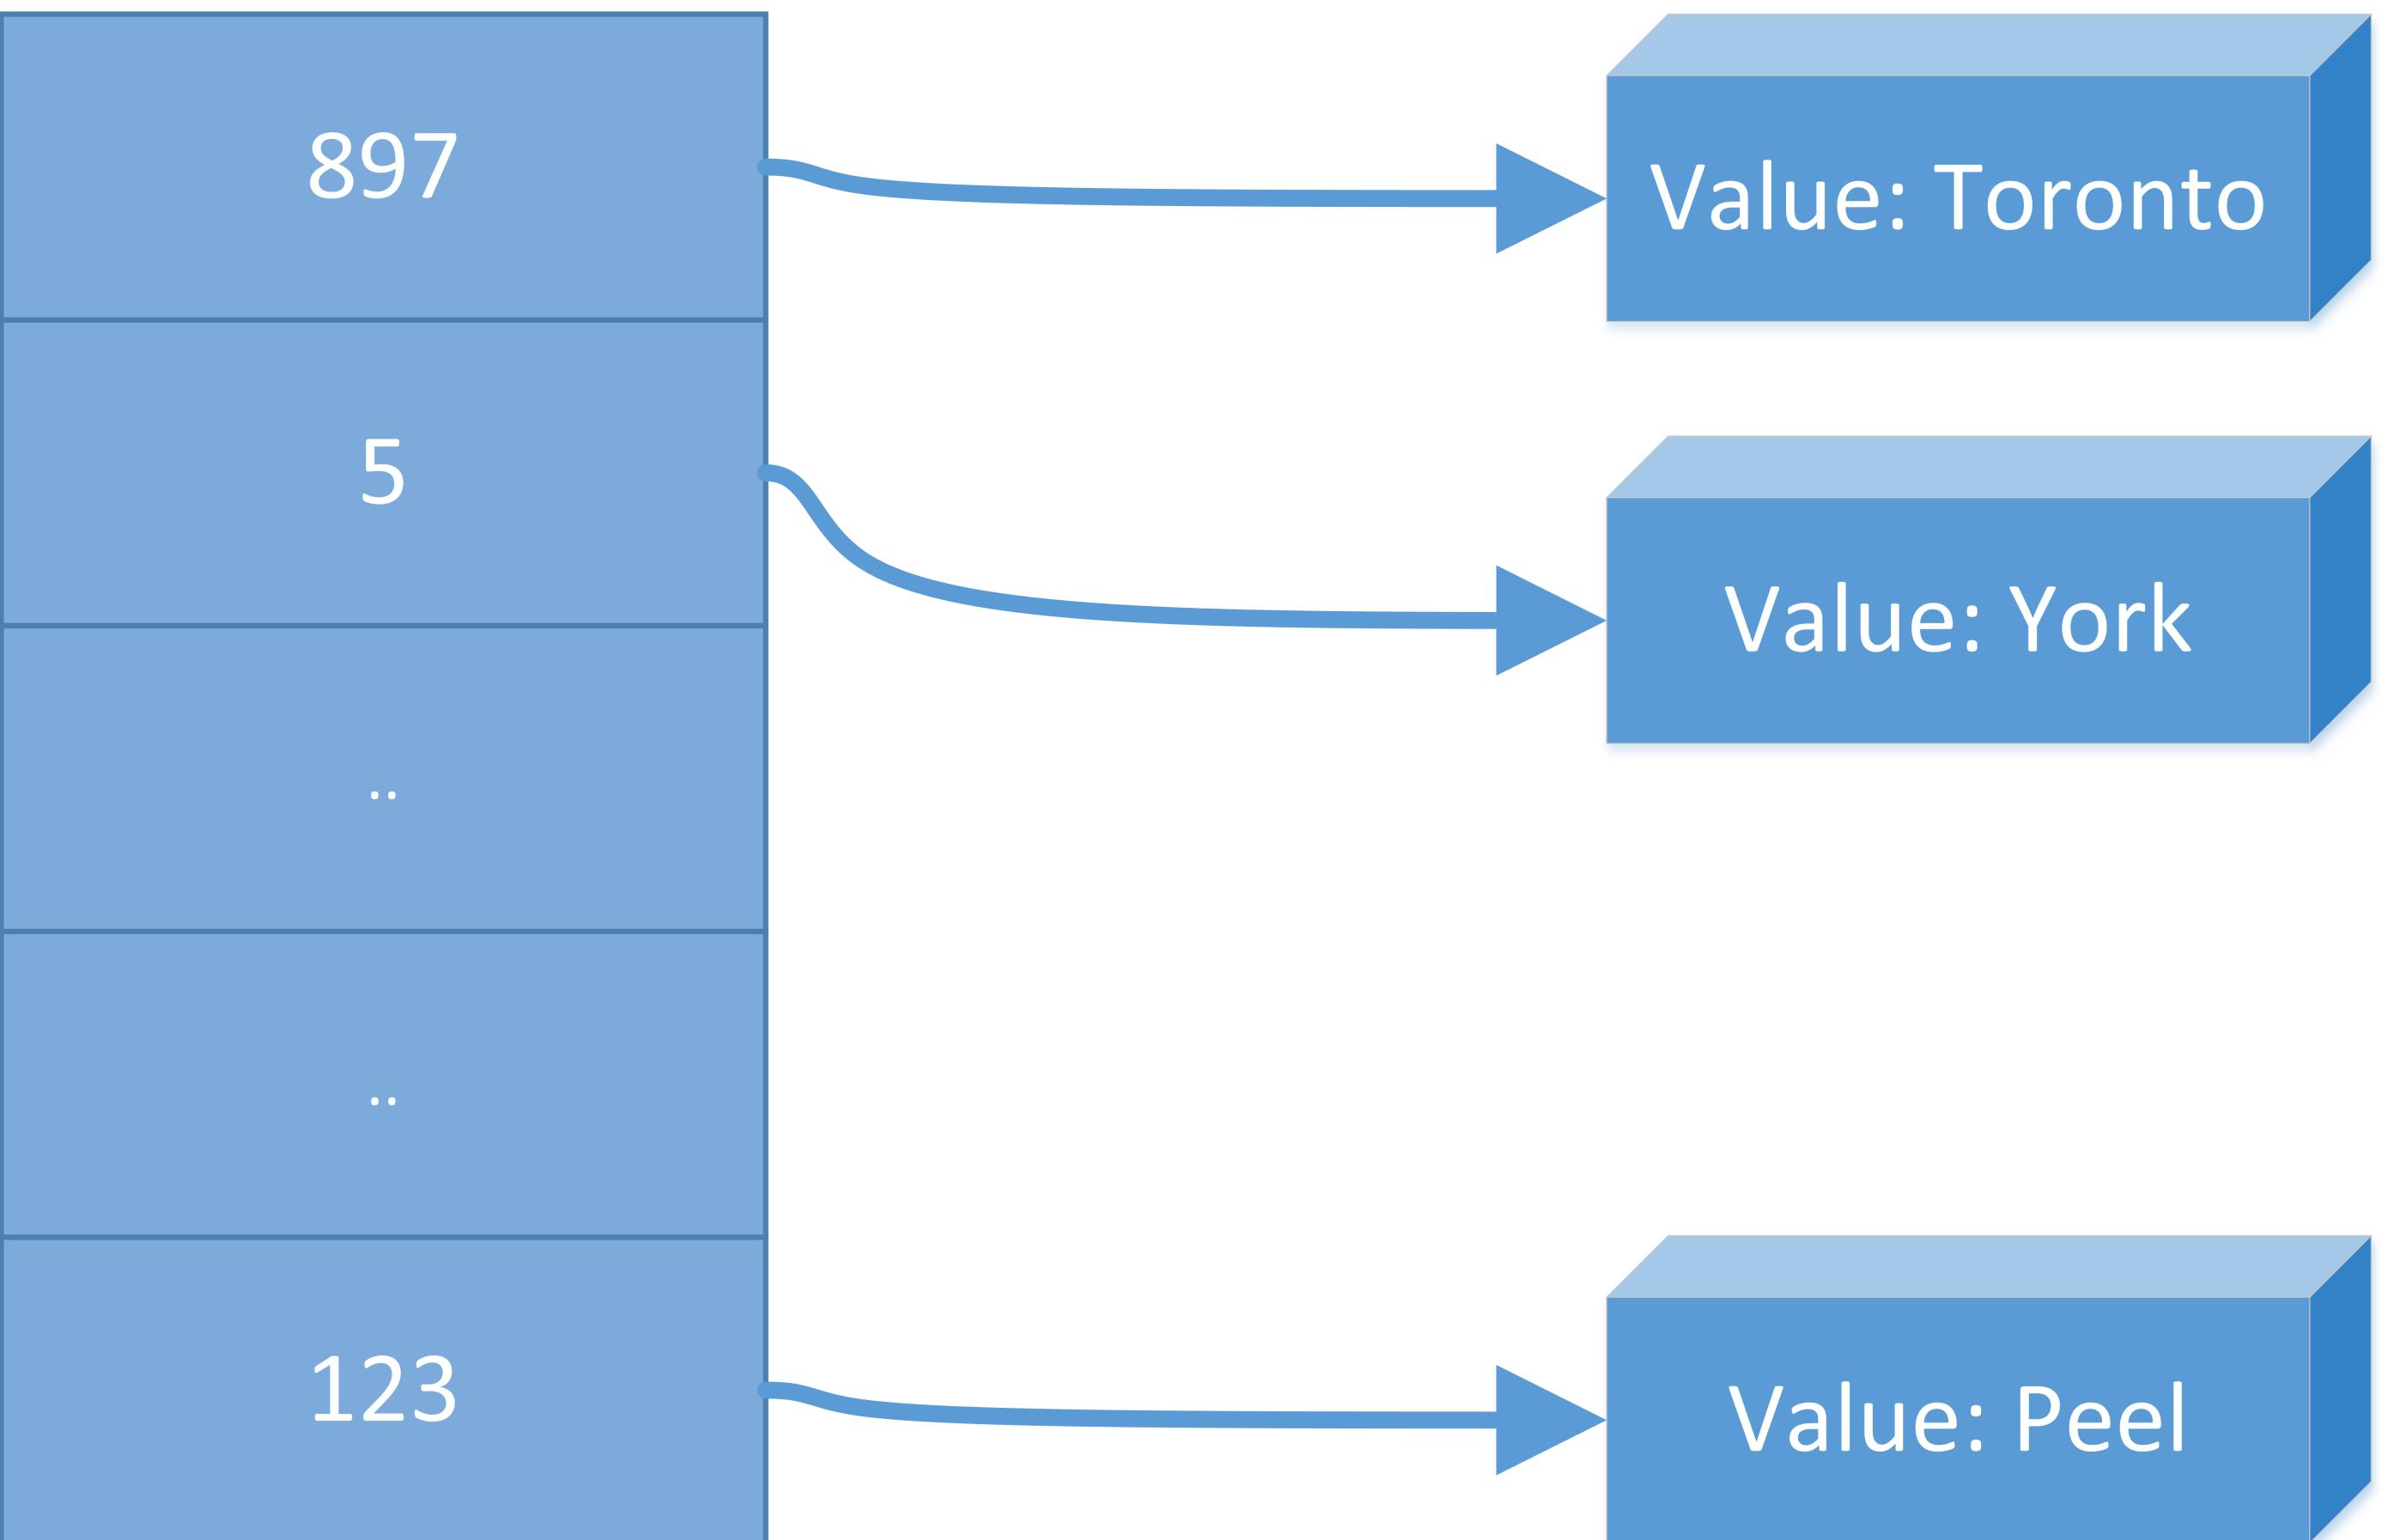

```
public class SetExample {  
    public static void main(String[] args) {  
  
        Set<String> set = new HashSet<>();  
        if (!set.add("testElement"))  
            throw new MyDuplicateException();  
  
    }  
}
```

# Set Implementations

# Map Interface

- maps keys to values (like a function)
- keys are unique
- each key is associated to one value

# Map Interface

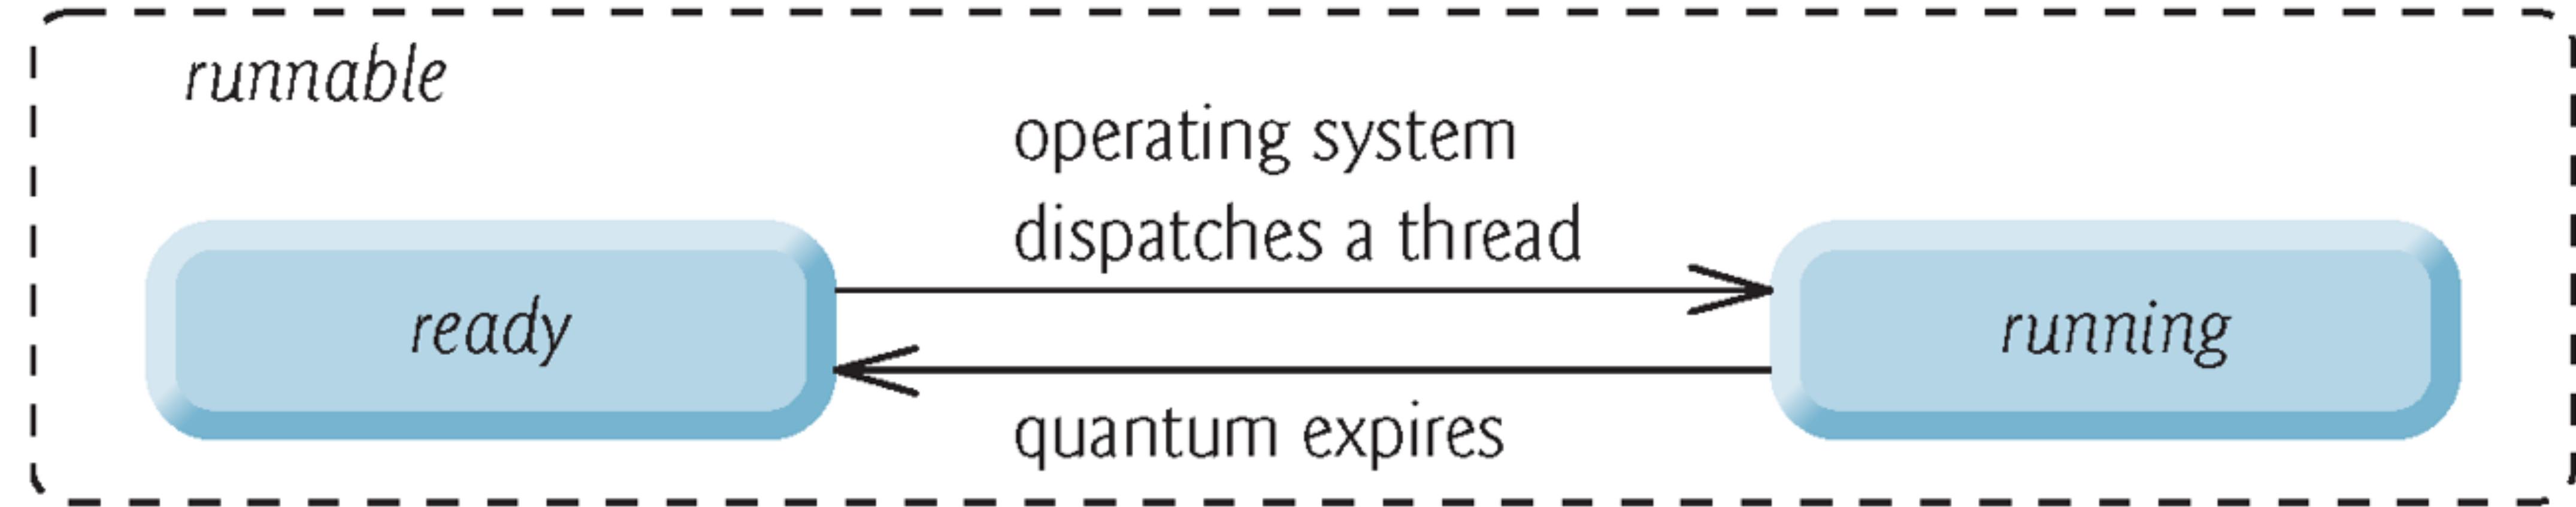

- maps keys to values
- keys are unique
- each key is associated to a value

```
public class MapDemo {  
    public static void main(String[] args) {  
  
        Map<String, Integer> c = new HashMap<>();  
        c.put("Alice", 1); c.put("Alice", 2);  
        int count = c.get("Alice");  
        count = c.getOrDefault("Barney", 0);  
  
        for (Map.Entry<String, Integer> entry : c.entrySet()) {  
            String key = entry.getKey();  
            Integer value = entry.getValue();  
            process(key, value);  
        }  
  
        public static void process(String k, Integer v) { .. }  
    }  
}
```

# Concurrency

# Concurrency

- when multiple tasks progress over time
- parallelism, when multiple tasks execute simultaneously
- thread, unit of execution with its own stack and program counter
- multithreading, multiple threads can execute while sharing system resources

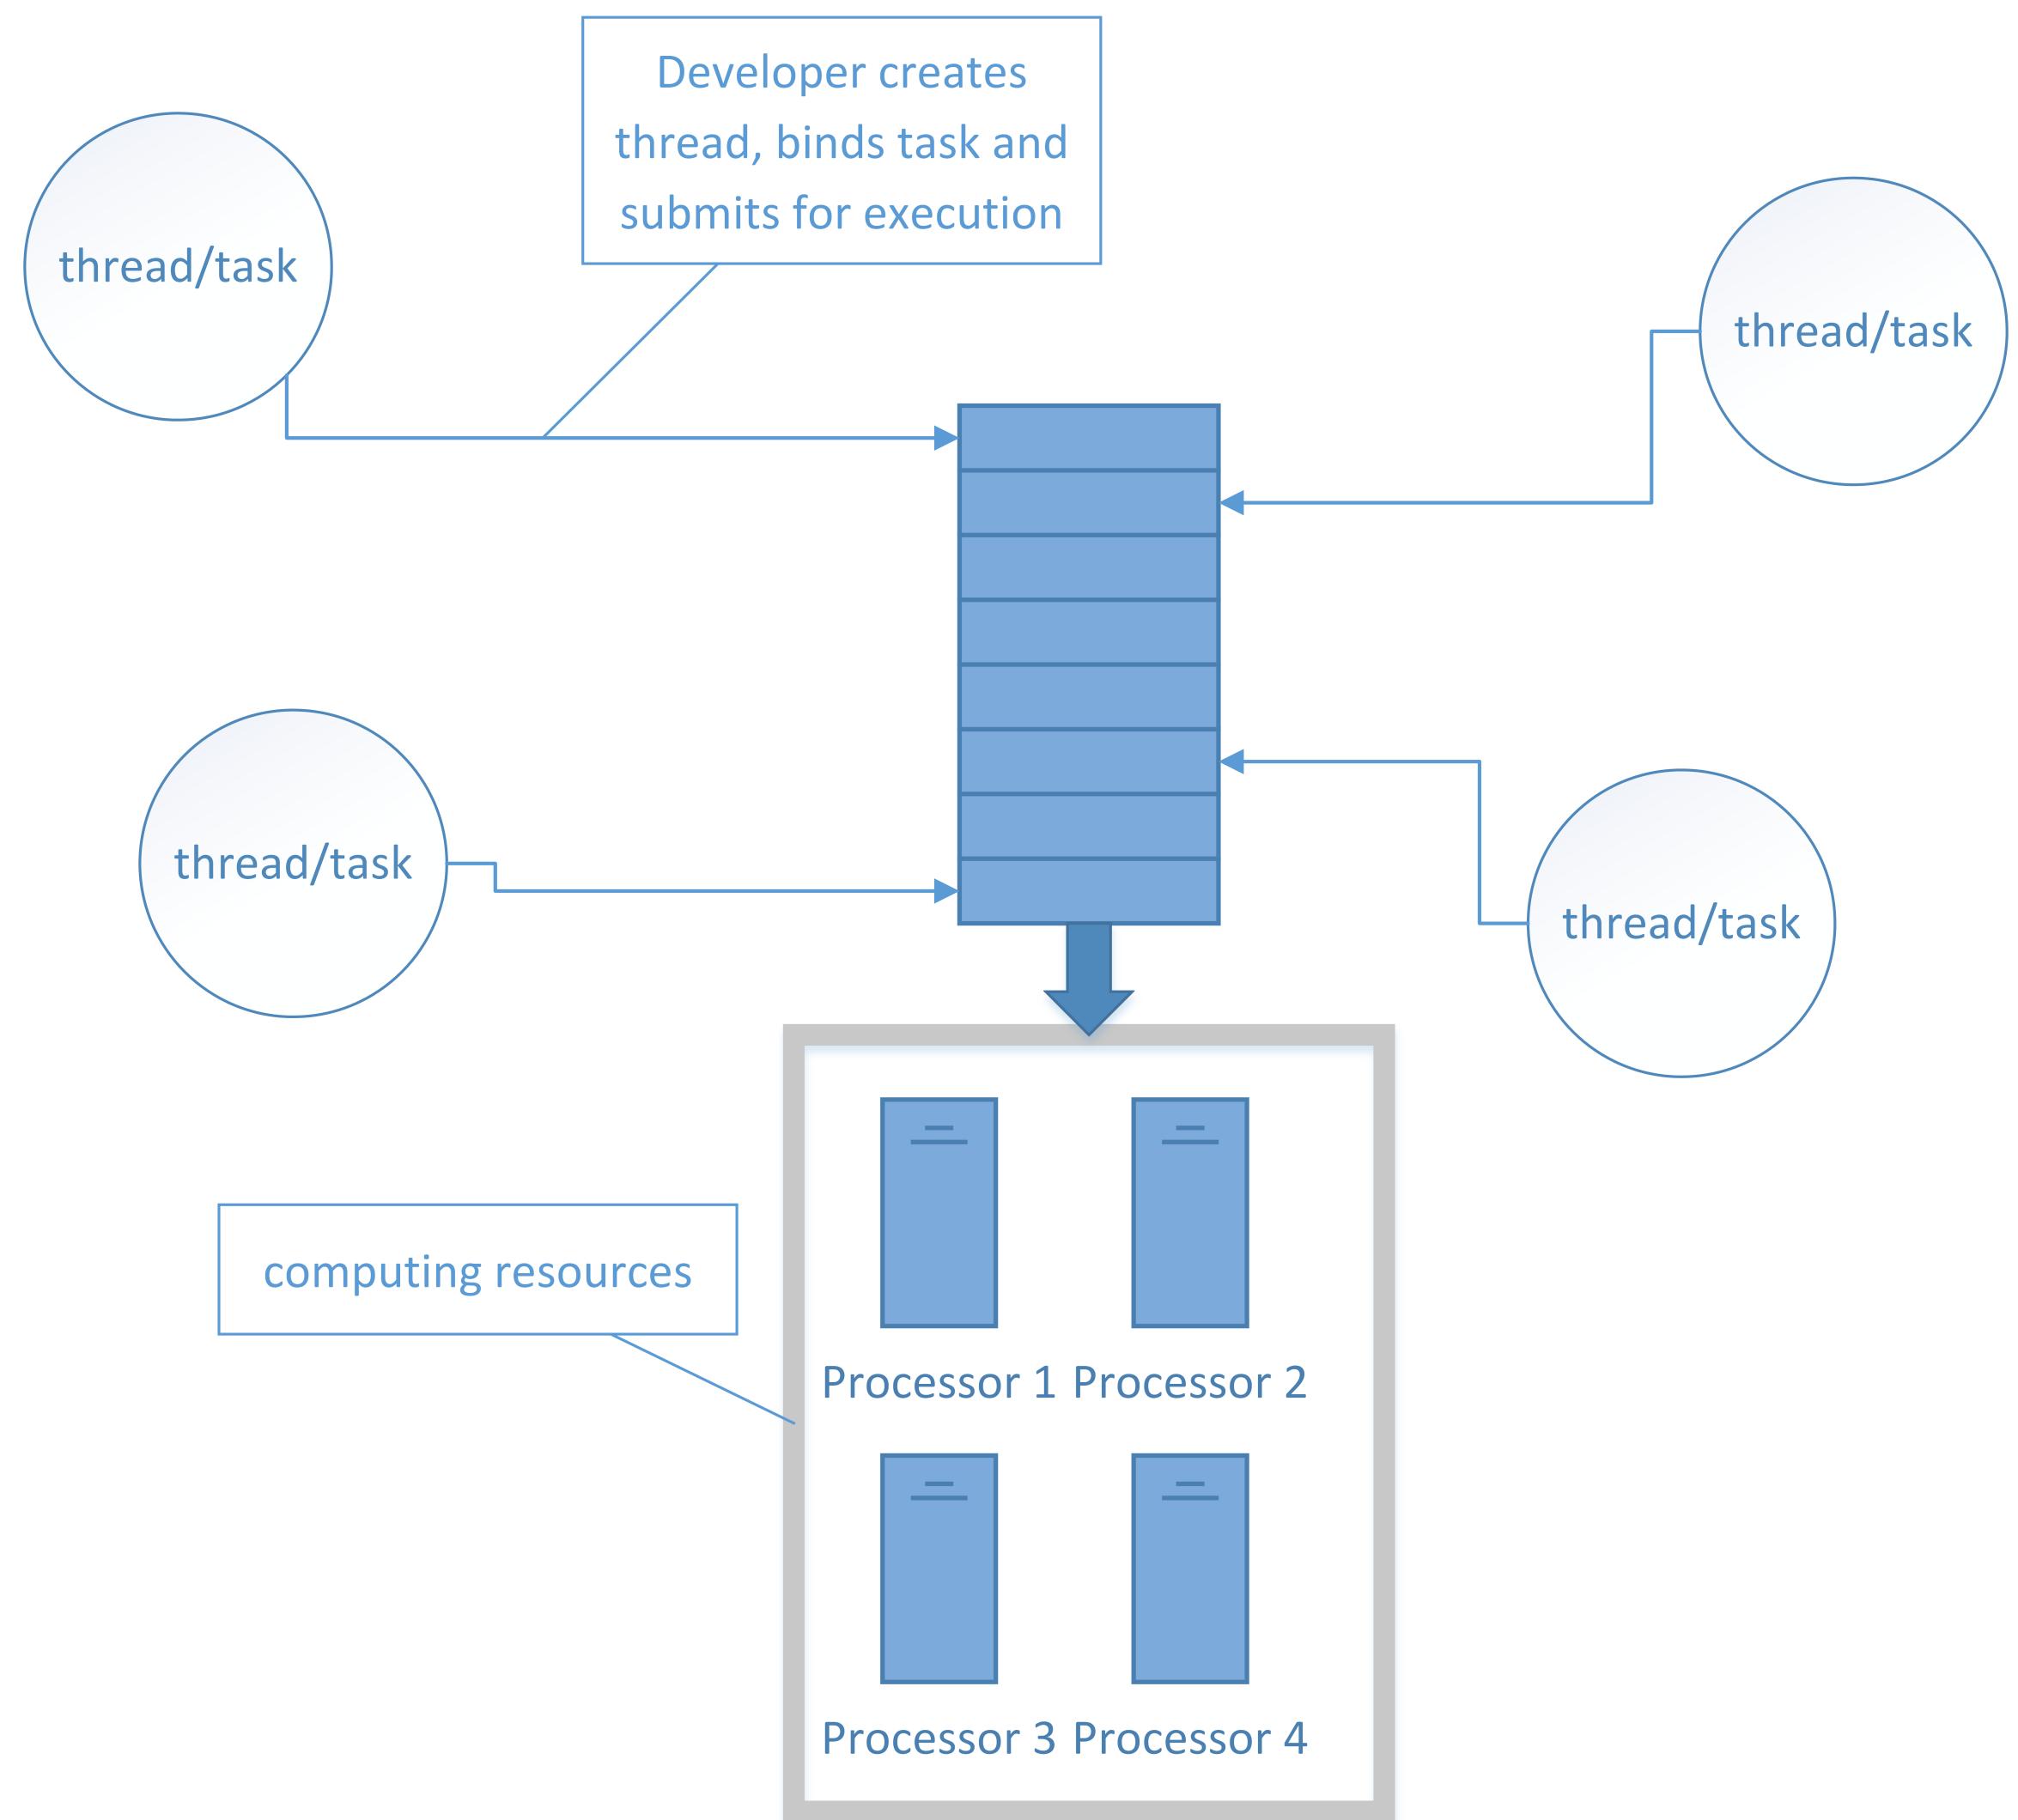

Operating system's internal view of Java's *runnable* state.

(*How to Program Java*, Deitel 2018)

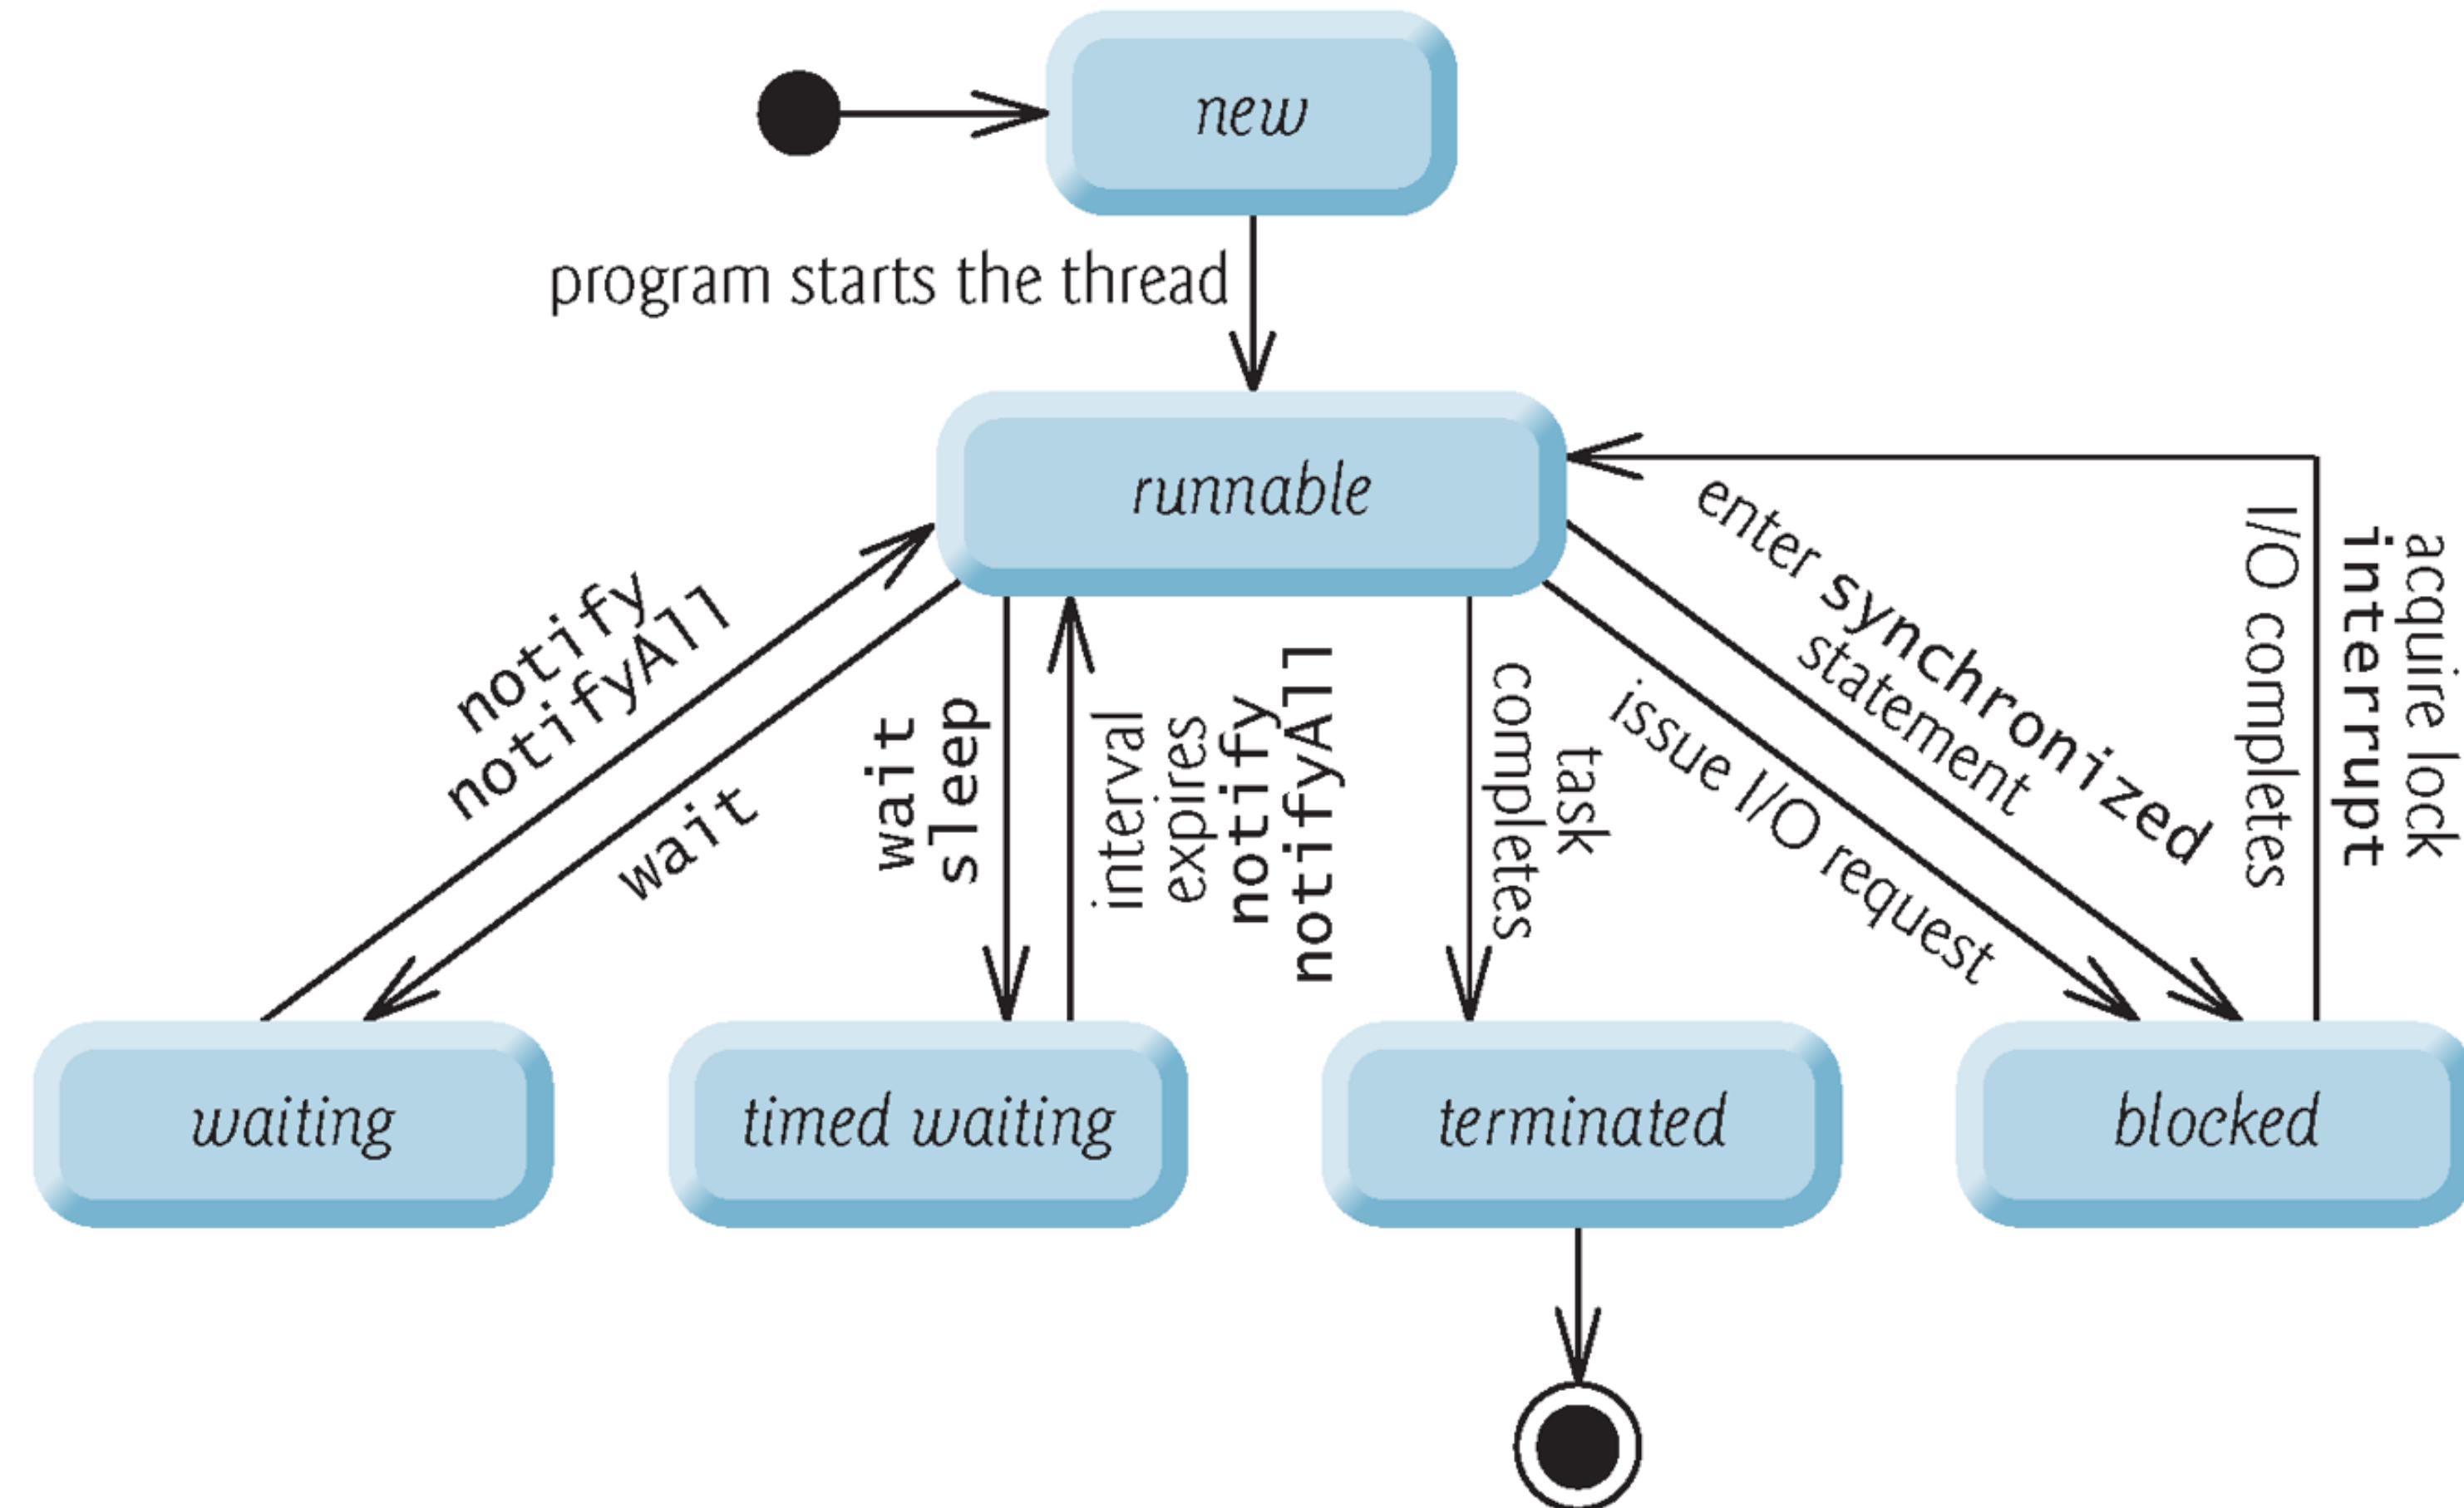

# Operating System View

“...programmer has no control over thread execution ...”

# Thread Object

“...create a thread to be selected for execution...”

(How to Program Java, Deitel 2018)

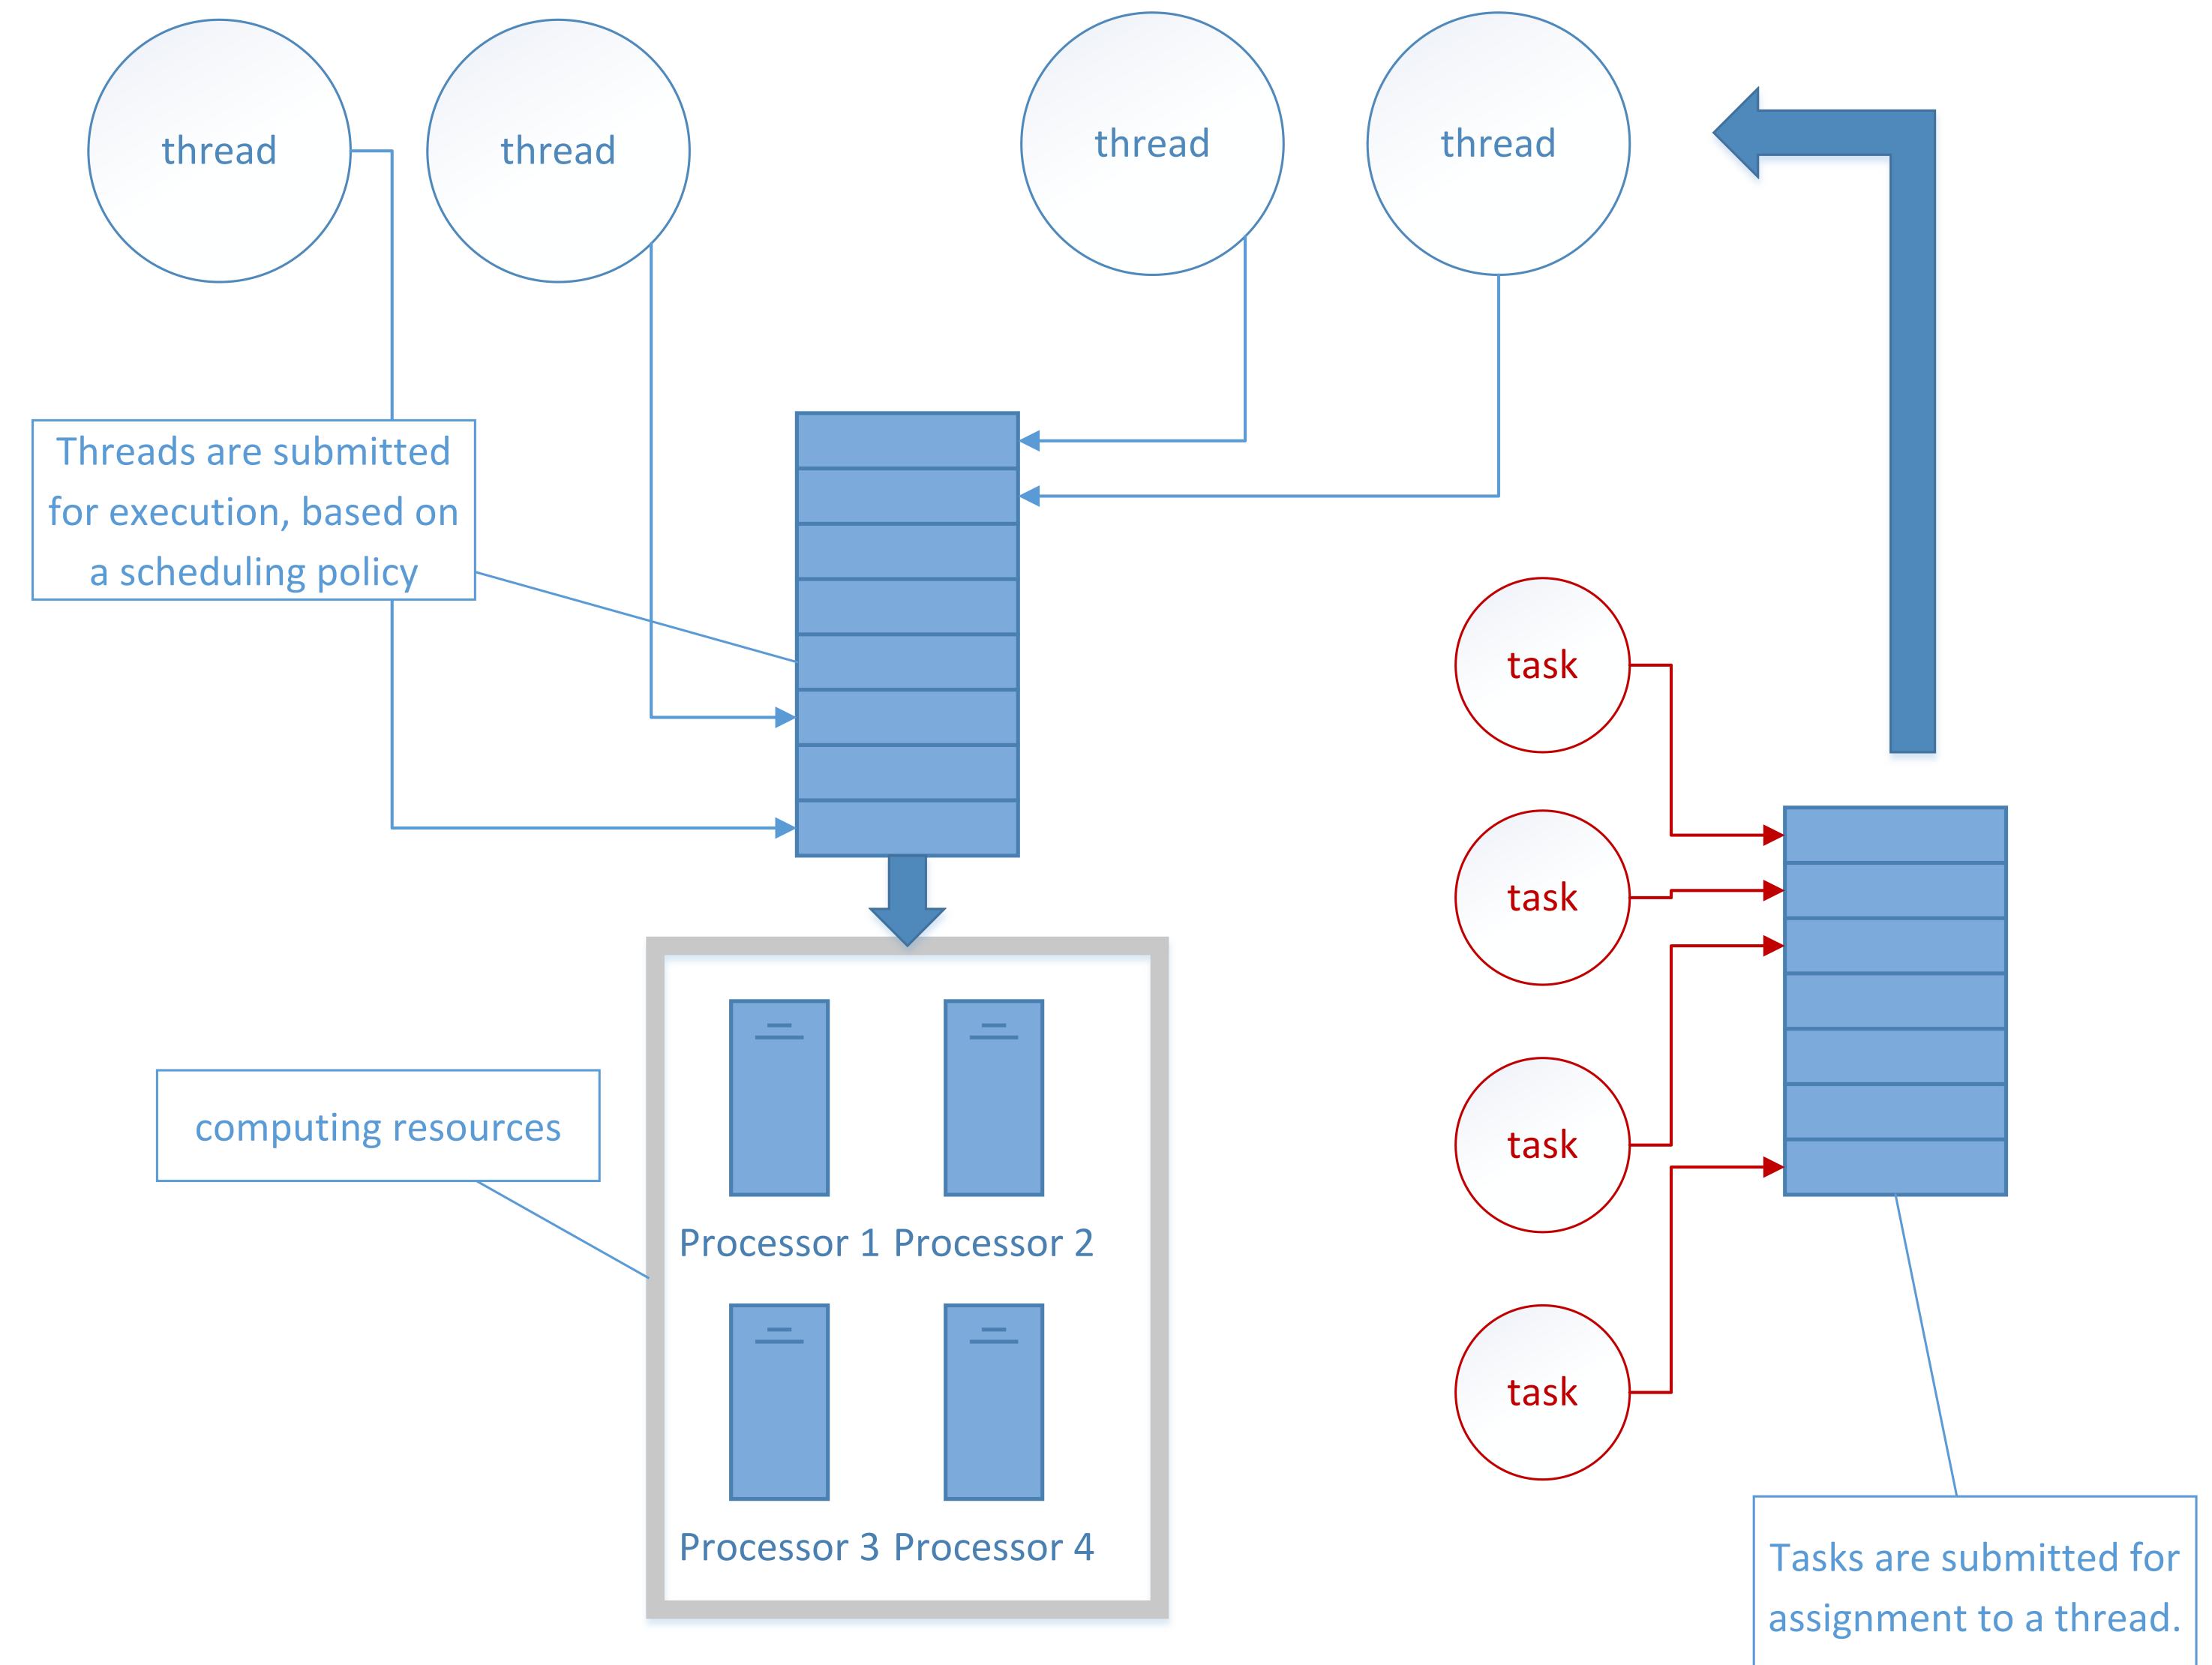

**Fig. 23.1** | Thread life-cycle UML state diagram.

# Thread Lifecycle

“...possible states during program execution...”

# Creating Concurrent Applications

- create tasks
- execute tasks with an Executor

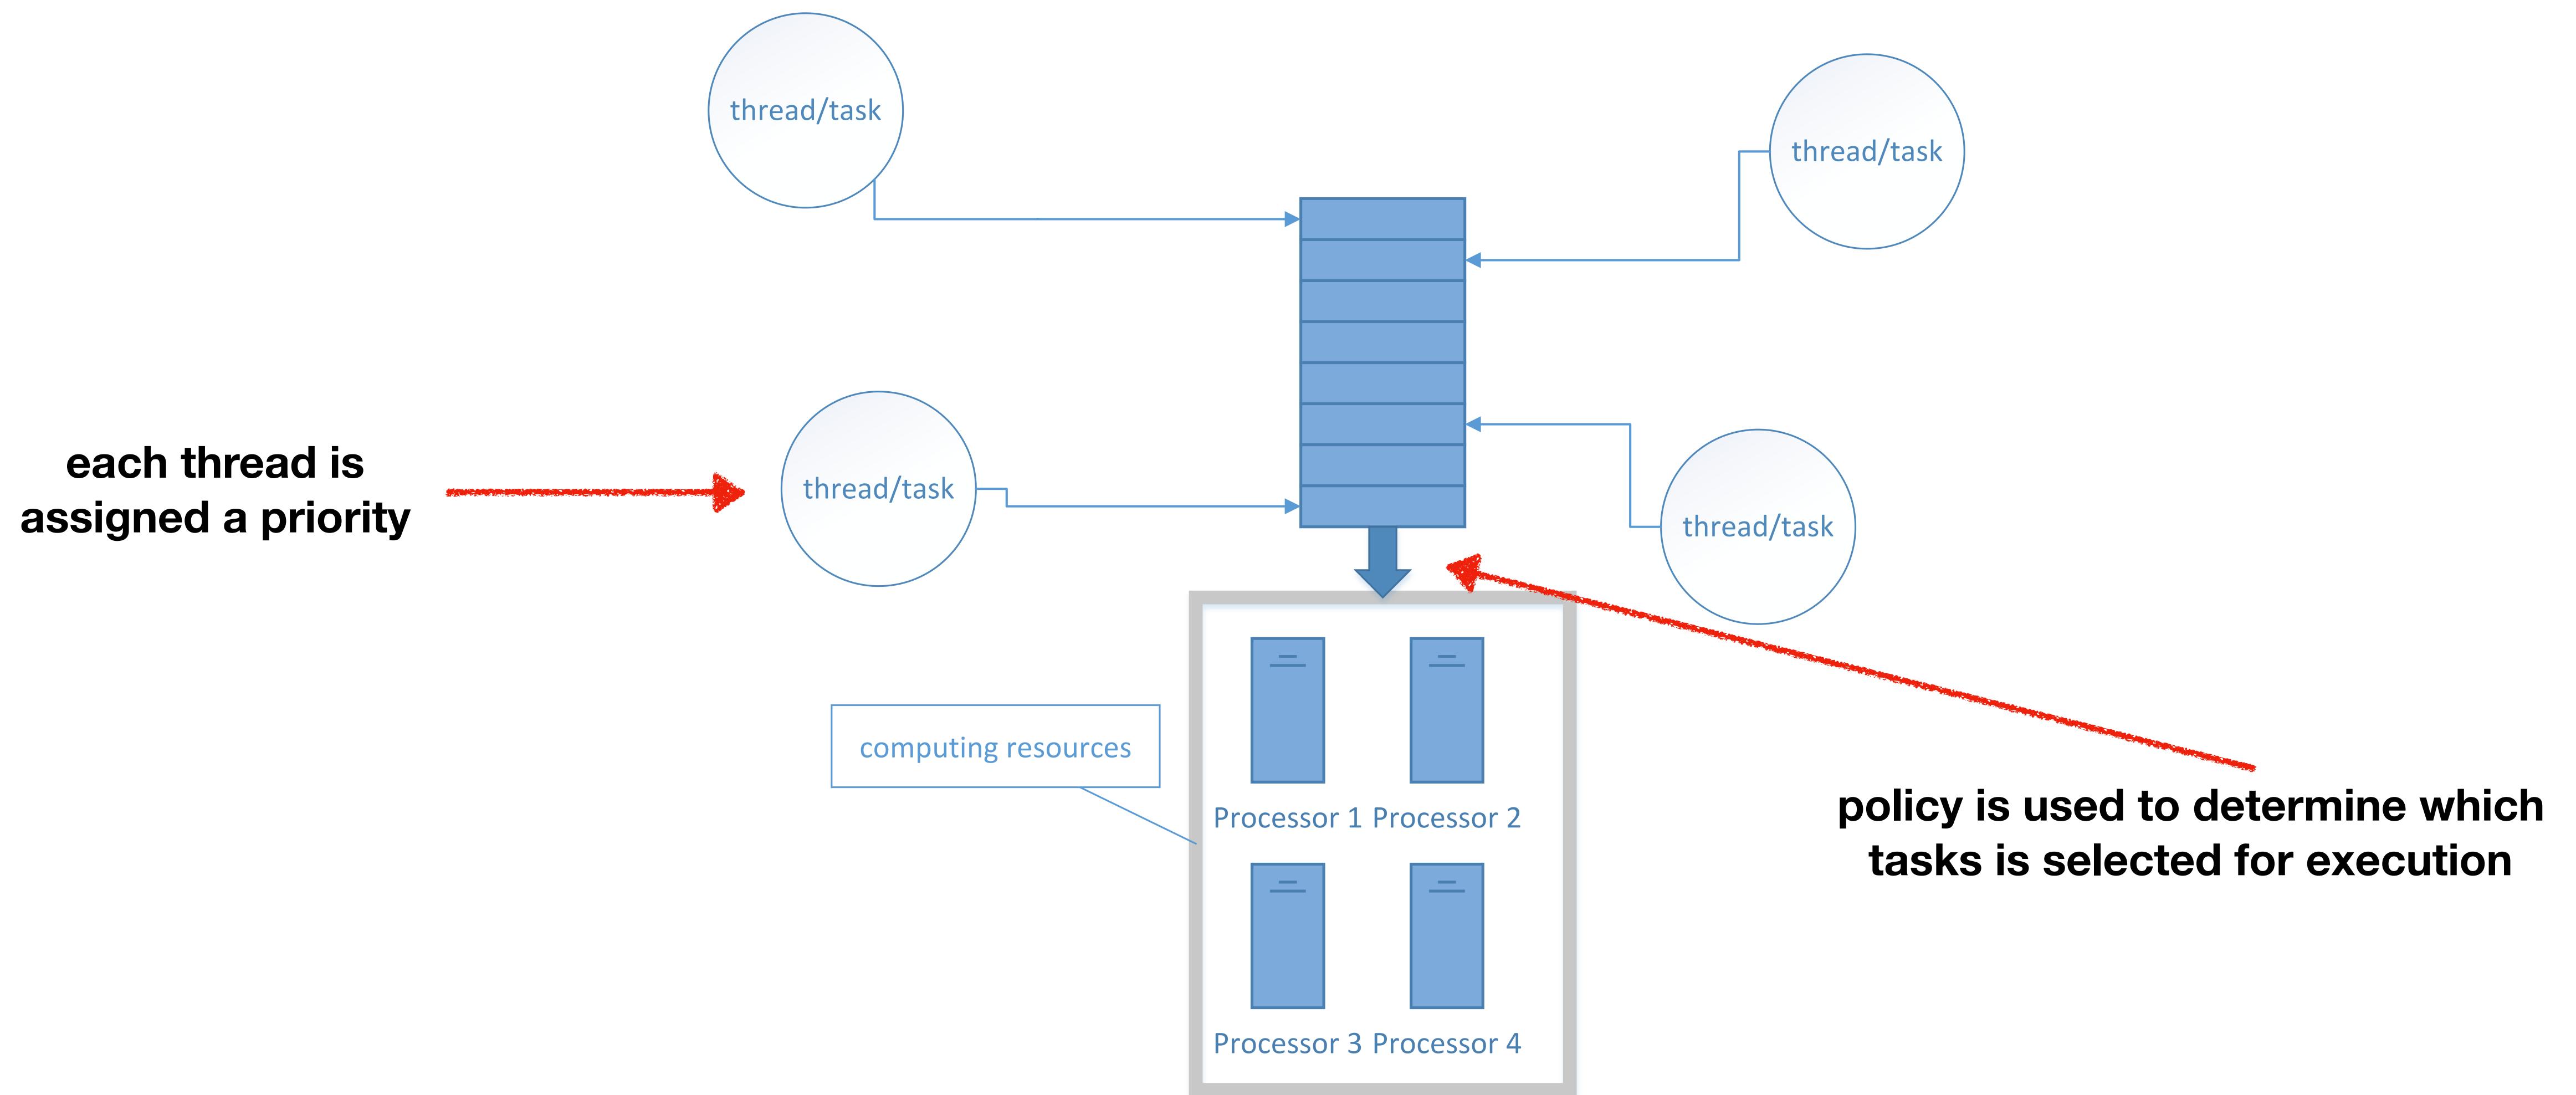

# Creating Concurrent Applications

```
class PrintTask implements Runnable {  
    @Override  
    public void run() { // task work }  
}  
  
public class TaskExecutor {  
    public static void main(String[] args) {  
  
        PrintTask t1 = new PrintTask("task1"); PrintTask t2 = new PrintTask("task2");  
        PrintTask t3 = new PrintTask("task3");  
  
        ExecutorService e = Executors.newCachedThreadPool();  
        // Create group of threads  
        e.execute(t1); e.execute(t2); e.execute(t3);  
        e.shutdown();  
  
    }  
}
```

A red bracket highlights the line `ExecutorService e = Executors.newCachedThreadPool();`. A red arrow points from this bracket to the text **create group of threads**.

A red bracket highlights the line `e.execute(t1); e.execute(t2); e.execute(t3);`. A red arrow points from this bracket to the text **task definition**.

# Starvation

“... when a task fails to progress over time...”

# Concurrency Challenges

| task1 commands               | order | task2 commands               |
|------------------------------|-------|------------------------------|
| put x into register (tmp1=0) | 1     |                              |
| add 1 (tmp1 = 1)             | 2     |                              |
| store result in x (x = tmp1) | 3     |                              |
|                              | 4     | put x into register (tmp2=1) |
|                              | 5     | add 1 (tmp2 = 2)             |
|                              | 6     | store result in x (x = tmp2) |

# Single Thread Environment

“...steps always occur in a particular order...”

| task1 commands               | order | task2 commands               |
|------------------------------|-------|------------------------------|
| put x into register (tmp1=0) | 1     |                              |
|                              | 2     | put x into register (tmp2=0) |
| add 1 (tmp1 = 1)             | 3     |                              |
|                              | 4     | add 1 (tmp2 = 1)             |
| store result in x (x = tmp1) | 5     |                              |
|                              | 6     | store result in x (x = tmp2) |

# Multithreaded Environment

“...steps are interleaved occur in an unpredictable order...”

# Race Condition

- when multiple threads access a shared resource
- results may differ each time
- access to resources must be synchronized to prevent corruption

```
public class SynchCounter {  
    private int c = 0; // mutable data  
  
    public synchronized void increment() { c++; }  
    public synchronized void decrement() { c--; }  
    public synchronized int value() { return c; }  
}
```

The diagram illustrates the concept of a race condition. A red arrow points from the text "mutable data" to the variable "c" in the code, highlighting it as the shared resource that can be modified simultaneously by multiple threads. Another red arrow points from the text "object lock" to the closing brace "}" of the class definition, indicating that the entire object is locked during any method execution to ensure consistency.

# Deadlock

- when a group of threads are waiting for each other to release a resource
